

COMMONWEALTH AGRICULTURAL BUREAUX

EXECUTIVE COUNCIL

Representing

Member

NEW ZEALAND.	E. Marsden, C.M.G., C.B.E., M.C., D.Sc., M.I.E.E., F.R.S. (Chairman).
UNION OF SOUTH AFRICA.	W. F. C. Morton (Vice-Chairman).
UNITED KINGDOM.	C. H. M. Wilcox, M.A.
CANADA.	Lt.-Col. J. G. Robertson, B.S.A., F.R.S.A.
AUSTRALIA.	J. E. Cummins, M.Sc., F.R.I.C.
INDIA.	H.E. The High Commissioner for India.
PAKISTAN.	A. M. Choudhury.
CEYLON.	H.E. The High Commissioner for Ceylon.
SOUTHERN RHODESIA.	J. E. C. Coventry, B.A., M.Sc.
COLONIAL TERRITORIES.	C. E. Lambert, C.M.G.

Sir Herbert Howard, B.A., Dip. For. (Secretary), Farnham House, Farnham Royal,
near Slough, Bucks.

LIAISON OFFICERS

UNITED KINGDOM.	A. B. Bartlett, Ministry of Agriculture and Fisheries, 1-4 Cambridge Terrace, Regent's Park, London, N.W.1.
CANADA.	H. L. Trueman, B.S.A., Director, Administrative Services, Department of Agriculture, Ottawa, Ontario, Canada.
AUSTRALIA.	W. Ives, M.Ec., A.I.C.A., Commonwealth Scientific and Industrial Research Organisation, 314 Albert Street, East Melbourne, C.2, Victoria, Australia.
NEW ZEALAND.	N. A. Marris, M.Sc., Department of Scientific and Industrial Research, Information Bureau, P.O. Box 8018, Govt. Buildings, Wellington, C.1, New Zealand.
UNION OF SOUTH AFRICA.	S. C. Potgieter, c/o Secretary for Agriculture, Agriculture Building, P.O. Vallis, Pretoria, Transvaal, Union of South Africa.
INDIA.	K. R. Damle, I.C.S., Vice-President, Indian Council of Agricultural Research, Raisina Road, New Delhi, India.
PAKISTAN.	Taskhir Ahmad, Ph.D. (Cantab.), Director, Department of Plant Protection, Government of Pakistan, Karachi.
CEYLON.	D. C. L. Amerasinghe, B.A. (Hons.) (London), Assistant Secretary, Ministry of Agriculture and Food, Colombo, Ceylon.
SOUTHERN RHODESIA.	G. R. Bates, Ph.D. (Lond.), Chief Botanist and Plant Pathologist, Department of Research and Specialist Services, P.O. Box 100, Causeway, Southern Rhodesia.
COLONIES.	Sir Geoffrey F. Clay, K.C.M.G., O.B.E., M.C., B.Sc., N.D.A., N.D.D. (Hons.), Agricultural Adviser to the Secretary of State, Colonial Office, Sanctuary Buildings, Gt. Smith Street, London, S.W.1.
ANGLO-EGYPTIAN SUDAN.	The Chief of the Research Division, Ministry of Agriculture, Wad Medani, Sudan.
REPUBLIC OF IRELAND.	S. M. Breathnach, Department of Agriculture, Dublin.

Books on Animal Nutrition and Allied Sciences

of all publishers supplied
from stock.

FOREIGN BOOKS NOT IN STOCK OBTAINED
TO ORDER UNDER BOARD OF TRADE LICENCE

Scientific Lending Library

ANNUAL SUBSCRIPTION, TOWN OR COUNTRY,
FROM TWENTY-FIVE SHILLINGS

Bi-monthly list of New Books and New Editions
added to the Library, sent post free to any
address on request.

The Library Catalogue revised to December,
1949. To subscribers, 17s. 6d. net. To non-
subscribers, 35s. net; postage 1s. 3d. Supplement
1950 to 1952. To subscribers 3s. net.
To non-subscribers 6s. net; postage 6d.

Second-Hand Books

A constantly changing large stock of second-
hand recent editions available. Large and small
collections bought.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, M.A., D.Sc.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG. PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d.

*Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.*

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

- *A REVIEW OF OBSERVATIONS ON DIET IN RELATION TO HEALTH AND DISEASE. H. Morris, 1933, 2, 665.
- *THE FIELD OF RESEARCH IN POULTRY NUTRITION. W. R. Graham, 1933, 2, 681.
- *QUALITATIVE AND QUANTITATIVE ASPECTS OF NUTRITION IN RELATION TO PUBLIC HEALTH. J. M. Hamill, 1933, 3, 1.
- *ULTRAVIOLET RADIATION IN RELATION TO HEALTH. J. H. Clark, 1933, 3, 13.
- *PELLAGRA. W. R. Aykroyd, 1933, 3, 337.
- *THE RÔLE OF FAT IN GLYCOGENESIS AND THE UTILISATION OF PROTEINS. F. Maignon, 1933, 3, 345.
- *THE DIGESTION AND UTILISATION OF CRUDE FIBRE. E. Mangold, 1934, 3, 647.
- *THE NUTRITIONAL ANAEMIAS OF MAN AND ANIMALS. L. S. P. Davidson and I. Leitch, 1934, 3, 901.
- *OSTEOMALACIA AND DIET. J. P. Maxwell, 1934, 4, 1.

- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (continued)

- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.
- THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.
- SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.
- *THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.
- *THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.
- *DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.
- THE AMOUNTS OF VITAMIN B₁ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.
- DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, 15, 591. Price 3s. 6d.
- THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.
- THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.
- MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.
- *PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.
- THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Hattiss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.
- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, 17, 291. Price 2s.
- THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, 17, 569. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- When ordering please quote authors' names and dates: e.g., *Morey (1936)*; *Fixsen and Roscoe (1940)*.
Orders and remittances should be sent to: THE SECRETARY, "NUTRITION ABSTRACTS AND REVIEWS,"
Rowett Institute, Bucksburn, Aberdeenshire, Scotland.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues annually six journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The six journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 8, No. 1, March, 1954. 30s. net

- V. SUBRAHMANYAN, H. B. N. MURTHY and M. SWAMINATHAN. Effects of partial replacement of rice, wheat or ragi (*Eleusine coracana*) by tuber flours on the nutritive value of poor vegetarian diets.
- H. B. N. MURTHY, M. SWAMINATHAN and V. SUBRAHMANYAN. Effects of partial replacement of rice in a rice diet by tapioca flour on the metabolism of nitrogen, calcium and phosphorus in adult human beings.
- SARANYA KUMARI REDDY, T. R. DORAISWAMY, A. N. SANKARAN, M. SWAMINATHAN and V. SUBRAHMANYAN. Effects on the general health and nutritional status of children of partial replacement of rice in a poor vegetarian diet by tapioca flour.
- R. A. McCANCE and W. M. V. STRANGEWAYS. Protein catabolism and oxygen consumption during starvation in infants, young adults and old men.
- J. G. BIERI and C. J. POLLARD. Studies of the site of conversion of β -carotene injected intravenously into rats.
- W. A. MANNELL and R. J. ROSSITER. Nutritional deficiency and Wallerian degeneration in the rat.
1. Effect of protein depletion on the concentration of nucleic acid and phospholipid in intact and sectioned nerves.
- W. A. MANNELL and R. J. ROSSITER. Nutritional deficiency and Wallerian degeneration in the rat.
2. Effect of thiamine deficiency on the concentration of nucleic acid and phospholipid in intact and sectioned nerves.
- J. J. C. HINTON and B. SHAW. The distribution of nicotinic acid in the rice grain.
- J. W. H. LUGE and F. P. ELLIS. Some water-soluble vitamins in the sweat of tropically-acclimatized European men.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

NUTRITION ABSTRACTS AND REVIEWS

COMMITTEE OF MANAGEMENT

Chairman: COL. E. BIRNIE REID, O.B.E., T.D., C.A.

Representing the Commonwealth Agricultural Bureaux Council:

MR. J. E. CUMMINS, M.Sc.

LT.-COL. J. G. ROBERTSON.

SIR HERBERT HOWARD.

Representing the Medical Research Council:

PROFESSOR SIR R. A. PETERS, M.C., M.D., F.R.S.

PROFESSOR B. S. PLATT, C.M.G., Ph.D., M.B.

HARRIETTE CHICK, D.B.E., D.Sc.

Representing the Reid Library:

PRINCIPAL T. M. TAYLOR, C.B.E., Q.C., M.A., LL.B.

PROFESSOR R. M. BARRER, D.Sc., Sc.D., F.R.I.C.

PROFESSOR E. W. H. CRUICKSHANK, M.D., D.Sc.,
M.R.C.P., F.R.S.E.

All communications should be addressed to the Secretary, "NUTRITION ABSTRACTS AND REVIEWS," ROWETT INSTITUTE, BUCKSBURN, ABERDEENSHIRE, SCOTLAND.

The Executive Council of the Commonwealth Agricultural Bureaux is a signatory to the Fair Copying Declaration, details of which can be obtained from the Royal Society, Burlington House, London, W.1.

CONSULTING EDITORS

LORD BOYD ORR, Newton of Stracathro, Brechin, Angus.

STB CHARLES J. MARTIN, Cambridge.

EDITORS

D. P. CUTHBERTSON, Rowett Research Institute, Aberdeen (*Chairman*).

H. CHICK, Lister Institute, London.

I. LEITCH, Commonwealth Bureau of Animal Nutrition, Aberdeen.

E. M. HUME, Lister Institute, London.

S. J. COWELL, University College Hospital Medical School, London.

J. A. B. SMITH, Hannah Dairy Research Institute, Kirkhill, Ayr.

Secretary :

J. S. THOMSON, Commonwealth Bureau of Animal Nutrition, Rowett Institute, Bucksburn, Aberdeenshire.

OVERSEAS CORRESPONDENT

U.S.A. H. H. MITCHELL, University of Illinois.

AUTHOR INDEX

** Nomenclature of Amino-Acids*

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

Books on *Animal Nutrition and Allied Sciences* of all publishers supplied

from stock.

FOREIGN BOOKS NOT IN STOCK OBTAINED
TO ORDER UNDER BOARD OF TRADE LICENCE

Scientific Lending Library

ANNUAL SUBSCRIPTION, TOWN OR COUNTRY,
FROM TWENTY-FIVE SHILLINGS

Bi-monthly list of New Books and New Editions
added to the Library, sent post free to any
address on request.

The Library Catalogue revised to December,
1949. To subscribers, 17s. 6d. net. To non-
subscribers, 35s. net; postage 1s. 3d. Supple-
ment 1950 to 1952. To subscribers 3s. net.
To non-subscribers 6s. net; postage 6d.

Second-Hand Books

A constantly changing large stock of second-
hand recent editions available. Large and small
collections bought.

Commonwealth Bureau of Animal Nutrition

Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, M.A., D.Sc.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG. PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d.

*Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.*

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

- *A REVIEW OF OBSERVATIONS ON DIET IN RELATION TO HEALTH AND DISEASE. H. Morris, 1933, 2, 665.
- *THE FIELD OF RESEARCH IN POULTRY NUTRITION. W. R. Graham, 1933, 2, 681.
- *QUALITATIVE AND QUANTITATIVE ASPECTS OF NUTRITION IN RELATION TO PUBLIC HEALTH. J. M. Hamill, 1933, 3, 1.
- *ULTRAVIOLET RADIATION IN RELATION TO HEALTH. J. H. Clark, 1933, 3, 13.
- *PELLAGRA. W. R. Aykroyd, 1933, 3, 337.
- *THE RÔLE OF FAT IN GLYCOGENESIS AND THE UTILISATION OF PROTEINS. F. Maignon, 1933, 3, 345.
- *THE DIGESTION AND UTILISATION OF CRUDE FIBRE. E. Mangold, 1934, 3, 647.
- *THE NUTRITIONAL ANAEMIAS OF MAN AND ANIMALS. L. S. P. Davidson and I. Leitch, 1934, 3, 901.
- *OSTEOMALACIA AND DIET. J. P. Maxwell, 1934, 4, 1.
- *THE INFLUENCE OF NUTRITION ON WOOL GROWTH. A. H. H. Fraser, 1934, 4, 9.
- DIABETES MELLITUS IN CHILDHOOD. R. Wagner, 1934, 4, 225.
- UNIVERSITY TEACHING OF NUTRITION AND DIETETICS IN THE UNITED STATES. M. S. Rose, 1935, 4, 439.
- THE BIOLOGICAL VALUE OF PROTEIN IN NUTRITION. M. A. B. Fixsen, 1935, 4, 447.
- THE BIOLOGICAL STANDARDISATION OF VITAMINS. K. H. Coward, 1935, 4, 705.
- VITAMINS AND MINERALS IN POULTRY NUTRITION. E. M. Cruickshank, 1935, 5, 1.
- NUTRITION INVESTIGATIONS IN ITALY. F. Bottazzi, 1935, 5, 275.
- THE RÔLE OF NUTRITION IN PREVENTION OF DISEASE IN FARM ANIMALS. A. H. H. Fraser, 1935, 5, 295.
- DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 5, 567.
- *A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, 5, 855.
- AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 6, 1.
- THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.
- THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.
- THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.
- NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.
- THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.
- THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, 7, 509.
- RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.
- *TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.
- *THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 281.
- THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.
- MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.
- PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.
- CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, 9, 253.
- *THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.
- TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.
- QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.
- VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.
- THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.
- THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, 10, 645.
- NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, 11, 3.
- INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, 11, 171.
- COMPONENTS OF THE VITAMIN B₂ COMPLEX. S. Lepkovsky, 1942, 11, 363.
- THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.
- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (continued)

- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.
- THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.
- SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.
- *THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.
- *THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.
- *DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.
- THE AMOUNTS OF VITAMIN B₁ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.
- DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, 15, 591. Price 3s. 6d.
- THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.
- THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.
- MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.
- *PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.
- *THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.
- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, 17, 291. Price 2s.
- THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, 17, 569. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, 23, 1. Price 2s.
- FAO. W. R. Aykroyd, 1953, 23, 229. Price 2s.
- ANTIBIOTICS IN NUTRITION. R. Braude, S. K. Kon and J. W. G. Porter, 1953, 23, 473. Price 3s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- SECULAR CHANGE IN THE HEIGHT OF BRITISH ADULTS. A. W. Boyne and I. Leitch, 1954, 24, 255. Price 2s.
- When ordering please quote authors' names and dates: e.g., Morey (1936); Fixsen and Roscoe (1940).
Orders and remittances should be sent to: THE SECRETARY, "NUTRITION ABSTRACTS AND REVIEWS,"
Rowett Institute, Bucksburn, Aberdeenshire, Scotland.*

MEDICAL RESEARCH COUNCIL

PLANT PROTEINS IN CHILD FEEDING

By R. F. A. Dean

Special Report Series No. 279

10s. net; by post, 10s. 6d.

VITAMIN C REQUIREMENT OF HUMAN ADULTS

by the Vitamin C Subcommittee of the Accessory Food Factors
Committee and Associated Workers

Special Report Series No. 280

17s. 6d. net; by post, 17s. 11d.

The publications of the Medical Research Council can be obtained from the following sources:—

LONDON: H.M. STATIONERY OFFICE, YORK HOUSE, KINGSWAY (or P.O. Box 569, S.E.1)

NEW YORK: BRITISH INFORMATION SERVICES, 30 ROCKEFELLER PLAZA

Through booksellers in any country

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues annually seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume I of the "Canadian Journal of Microbiology" will consist of 9 numbers, *i.e.*, August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 8, No. 2, June, 1954. 30s. net

W. T. C. BERRY, P. J. COWIN and D. R. DAVIES. A relationship between body fat and plasma pseudo-cholinesterase.

DAGMAR C. WILSON. The nutrition of schoolgirls in Northern Nigeria.

DAGMAR C. WILSON. Goitre in Ceylon and Nigeria.

E. R. BRANSBY. The nutrition of male industrial workers with particular reference to intake and expenditure of calories.

T. G. TAYLOR and J. H. MOORE. Skeletal depletion in hens laying on a low-calcium diet.

ANNE S. COLE and PATRICIA P. SCOTT. Tissue changes in the adult tryptophan-deficient rat.

ANCEL KEYS and MARGARET HANEY KEYS. Serum cholesterol and the diet in clinically health men at Slough near London.

ELSIE M. WIDDOWSON, O. G. EDHOLM and R. A. McCANCE. The food intake and energy expenditure of cadets in training.

MARGARET W. STANIER and E. G. HOLMES. Malnutrition in African adults. 1. Serum proteins, cholinesterase, and protein-bound lipid.

W. T. C. BERRY. Myotatic irritability.

JOYCE BUXTON, HILARY M. GRUNDY, DAGMAR C. WILSON and D. G. JAMISON. The absence of anti-thyroid properties for rats in two types of groundnut oil in common use in Nigeria.

E. G. HOLMES, E. R. JONES and MARGARET W. STANIER. Malnutrition in African adults. 2. Protein storage.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

NUTRITION ABSTRACTS AND REVIEWS

COMMITTEE OF MANAGEMENT

Chairman: COL. E. BIRNIE REID, O.B.E., T.D., C.A.

Representing the Commonwealth Agricultural Bureaux Council:

LT.-COL. J. G. ROBERTSON.

SIR HERBERT HOWARD.

Representing the Medical Research Council:

PROFESSOR SIR RUDOLPH PETERS, M.C., M.D., F.R.S.

PROFESSOR B. S. PLATT, C.M.G., PH.D., M.B.

HARRIETTE CHICK, D.B.E., D.Sc.

Representing the Reid Library:

PRINCIPAL T. M. TAYLOR, C.B.E., Q.C., M.A., LL.B.

PROFESSOR R. M. BARRER, D.Sc., Sc.D., F.R.I.C.

PROFESSOR E. W. H. CRUICKSHANK, M.D., D.Sc.,
M.R.C.P., F.R.S.E.

All communications should be addressed to the Secretary, "NUTRITION ABSTRACTS AND REVIEWS," ROWETT INSTITUTE, BUCKSBURN, ABERDEENSHIRE, SCOTLAND.

The Executive Council of the Commonwealth Agricultural Bureaux is a signatory to the Fair Copying Declaration, details of which can be obtained from the Royal Society, Burlington House, London, W.1.

CONSULTING EDITORS

LORD BOYD ORR, Newton of Stracathro, Brechin, Angus.
SIR CHARLES J. MARTIN, Cambridge.

EDITORS

D. P. CUTHBERTSON, Rowett Research Institute, Aberdeen (*Chairman*).
H. CHICK, Lister Institute, London.
I. LEITCH, Commonwealth Bureau of Animal Nutrition, Aberdeen.
E. M. HUME, Lister Institute, London.
S. J. COWELL, University College Hospital Medical School, London.
J. A. B. SMITH, Hannah Dairy Research Institute, Kirkhill, Ayr.

Secretary :

J. S. THOMSON, Commonwealth Bureau of Animal Nutrition, Rowett
Institute, Bucksburn, Aberdeenshire.

OVERSEAS CORRESPONDENT

U.S.A. H. H. MITCHELL, University of Illinois

AUTHOR INDEX

* Nomenclature of Amino-Acids

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, M.A., D.Sc.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG. PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I.: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

- *A REVIEW OF OBSERVATIONS ON DIET IN RELATION TO HEALTH AND DISEASE. H. Morris, 1933, 2, 665.
- *THE FIELD OF RESEARCH IN POULTRY NUTRITION. W. R. Graham, 1933, 2, 681.
- *QUALITATIVE AND QUANTITATIVE ASPECTS OF NUTRITION IN RELATION TO PUBLIC HEALTH. J. M. Hamill, 1933, 3, 1.
- *ULTRAVIOLET RADIATION IN RELATION TO HEALTH. J. H. Clark, 1933, 3, 13.
- *PELLAGRA. W. R. Aykroyd, 1933, 3, 337.
- *THE RÔLE OF FAT IN GLYCOGENESIS AND THE UTILISATION OF PROTEINS. F. Maignon, 1933, 3, 345.
- *THE DIGESTION AND UTILISATION OF CRUDE FIBRE. E. Mangold, 1934, 3, 647.
- *THE NUTRITIONAL ANAEMIAS OF MAN AND ANIMALS. L. S. P. Davidson and I. Leitch, 1934, 3, 901.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues annually seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume I of the "Canadian Journal of Microbiology" will consist of 9 numbers, *i.e.*, August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 8, No. 3, September, 1954. 30s. net

- E. R. BRANSBY and J. E. FOTHERGILL. The diets of young children.
- N. G. BAPTIST. Determination of essential amino-acids in some Ceylon vegetables.
- N. G. BAPTIST. Essential amino-acids of some common tropical legumes and cereals.
- SUSAN HOLMES. A qualitative study on family meals in Western Samoa with special reference to child nutrition.
- A. BONDI and A. SPANDORF. The action of the digestive enzymes of the carp.
- S. O. MANN, FRANCIS M. MASSON and A. E. OXFORD. Effect of feeding aureomycin to calves upon the establishment of their normal rumen microflora and microfauna.
- R. C. GARRY, A. W. SLOAN, J. B. DE V. WEIR and MARY WISHART. The concentration of haemoglobin in the blood of young adult men and women: the effect of administering small doses of iron for prolonged periods.
- N. L. FERGUSON. Changes in the liver fat of the pregnant sheep at different levels of nutrition and during starvation.
- E. AÆS-JØRGENSEN and H. DAM. The role of fat in the diet of rats. 1. Influence of lard hydrogenated peanut oil and absence of dietary fat on growth, food and fluid consumption and urine production. 2. Influence of dietary fats on growth. 3. Influence on kind and quantity of fat on food and fluid consumption and urine production. 4. Influence of supplementation with raw skim milk, linoleic acid or both on growth. 5. Influence of supplementation with raw skim milk, linoleic acid or both on food and fluid consumption and urine production.
- H. A. P. C. OOMEN. Xerophthalmia in the presence of kwashiorkor.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

NUTRITION ABSTRACTS AND REVIEWS

COMMITTEE OF MANAGEMENT

Chairman: COL. E. BIRNIE REID, O.B.E., T.D., C.A.

Representing the Commonwealth Agricultural Bureaux Council:

MR. W. F. C. MORTON.

LT.-COL. J. G. ROBERTSON.

SIR HERBERT HOWARD.

Representing the Medical Research Council:

PROFESSOR SIR RUDOLPH PETERS, M.C., M.D., F.R.S.

PROFESSOR B. S. PLATT, C.M.G., PH.D., M.B.

HARRIETTE CHICK, D.B.E., D.Sc.

Representing the Reid Library:

PRINCIPAL SIR THOMAS TAYLOR, C.B.E., Q.C., M.A., LL.B.

PROFESSOR R. M. BARRER, D.Sc., Sc.D., F.R.I.C.

PROFESSOR E. W. H. CRUICKSHANK, M.D., D.Sc.,
M.R.C.P., F.R.S.E.

All communications should be addressed to the Secretary, "NUTRITION ABSTRACTS AND REVIEWS," ROWETT INSTITUTE, BUCKSBURN, ABERDEENSHIRE, SCOTLAND.

The Executive Council of the Commonwealth Agricultural Bureaux is a signatory to the Fair Copying Declaration, details of which can be obtained from the Royal Society, Burlington House, London, W.1.

CONSULTING EDITORS

LORD BOYD ORR, Newton of Stracathro, Brechin, Angus.

SIR CHARLES J. MARTIN, Cambridge.

EDITORS

D. P. CUTHBERTSON, Rowett Research Institute, Aberdeen (*Chairman*).

H. CHICK, Lister Institute, London.

I. LEITCH, Commonwealth Bureau of Animal Nutrition, Aberdeen.

E. M. HUME, Lister Institute, London.

S. J. COWELL, University College Hospital Medical School, London.

J. A. B. SMITH, Hannah Dairy Research Institute, Kirkhill, Ayr.

Secretary :

J. S. THOMSON, Commonwealth Bureau of Animal Nutrition, Rowett Institute, Bucksburn, Aberdeenshire.

OVERSEAS CORRESPONDENT

U.S.A. H. H. MITCHELL, University of Illinois.

AUTHOR INDEX

** Nomenclature of Amino-Acids*

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, M.A., D.Sc.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG. PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d.

*Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.*

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

- DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 5, 567.
- *A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, 5, 855.
- AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 6, 1.
- THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.
- THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.
- THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.
- NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.
- THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.
- THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Ott and I. Leitch, 1938, 7, 509.
- RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.
- *TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.
- *THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 281.
- THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.
- MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.
- PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.
- CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, 9, 253.
- *THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.
- TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.
- QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.
- VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.
- THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.
- THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, 10, 645.
- NUTRITION AND HUMAN WELFARE. J. B. Ott, 1941, 11, 3.
- INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, 11, 171.
- COMPONENTS OF THE VITAMIN B₂ COMPLEX. S. Lepkovsky, 1942, 11, 363.
- THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.
- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- *SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.
- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.
- THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.
- SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.
- *THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.
- *THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.
- *DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.
- THE AMOUNTS OF VITAMIN B₂ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.
- DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, 15, 591. Price 3s. 6d.
- THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.
- THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.
- MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.
- *PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.
- *THE RÔLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (*continued*)

- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, 17, 291. Price 2s.
- THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, 17, 569. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Hattie Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, 23, 1. Price 2s.
- FAO. W. R. Aykroyd, 1953, 23, 229. Price 2s.
- ANTIBIOTICS IN NUTRITION. R. Braude, S. K. Kon and J. W. G. Porter, 1953, 23, 473. Price 3s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- SECULAR CHANGE IN THE HEIGHT OF BRITISH ADULTS. A. W. Boyne and I. Leitch, 1954, 24, 255. Price 2s.
- THE SEA AND WORLD FOOD SUPPLIES. D. B. Finn, 1954, 24, 487. Price 2s.
- LAND USE AND DEVELOPMENT IN AUSTRALIA. C. G. Stephens, 1954, 24, 731. Price 2s.
- When ordering please quote authors' names and dates: e.g., Morey (1936); Fissen and Roscoe (1940).
Orders and remittances should be sent to: THE SECRETARY, "NUTRITION ABSTRACTS AND REVIEWS,"
Rowett Institute, Bucksburn, Aberdeenshire, Scotland.

Malnutrition in African Mothers, Infants and Young Children

Report of the Second Inter-African Conference on Nutrition, held under the auspices of the Commission for Technical Co-operation in Africa South of the Sahara (CCTA) at Fajara, Gambia, in November, 1952.

The report includes papers on the clinical aspects, aetiology, pathology, dietary factors,

biochemistry, treatment and prevention of malnutrition, with emphasis on protein deficiency. Discussions of these papers by delegates to the conference and observers from the Food and Agriculture Organization and World Health Organization are reproduced in detail.

Price 25s. By post 25s. 6d.

HER MAJESTY'S STATIONERY OFFICE

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues annually seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume I of the "Canadian Journal of Microbiology" will consist of 9 numbers, *i.e.*, August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 8, No. 4, 1954. 30s. net

Obituary Notice (Sir Jack Cecil Drummond).

GWENETH M. CHAPPELL. Food waste and loss of weight in cooking.

MARGARET E. GREGORY. The microbiological assay of 'vitamin B₁₂' in the milk of different animal species.

V. SUBRAHMANYAN, SARANYA KUMARI REDDY, M. N. MOORJANI, GOWRI SUR, T. R. DORAISWAMY, A. N. SANKARAN, D. S. BHATIA and M. SWAMINATHAN. Supplementary value of vegetable-milk curds in the diet of children.

R. S. ROBERTS. The nutritional properties of killed *Bacterium coli*.

G. E. LAMMING, D. H. M. WOOLLAM and J. W. MILLEN. Hydrocephalus in young rabbits associated with maternal vitamin A deficiency.

H. HELLER. Intestinal absorption of glucose in protein-deficient and in starving rats.

CECILIA D. DICKINSON and PATRICIA P. SCOTT. Effects of adding penicillin and aureomycin to the diet of cats.

V. RAMALINGASWAMI and H. M. SINCLAIR. Polycythaemia in pyridoxin deficiency in the rat.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

Zentralblatt für Veterinärmedizin

Prof. Dr. M. LERCHE
Free University, Berlin

Edited by
and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume. Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets. Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

NUTRITION ABSTRACTS AND REVIEWS

COMMITTEE OF MANAGEMENT

Chairman: COL. E. BIRNIE REID, O.B.E., T.D., C.A.

Representing the Commonwealth Agricultural Bureaux Council:

MR. W. F. C. MORTON.
LT.-COL. J. G. ROBERTSON.
SIR HERBERT HOWARD.

Representing the Medical Research Council:

PROFESSOR SIR RUDOLPH PETERS, M.C., M.D., F.R.S.
PROFESSOR B. S. PLATT, C.M.G., PH.D., M.B.
HARRIETTE CHICK, D.B.E., D.Sc.

Representing the Reid Library:

PRINCIPAL SIR THOMAS TAYLOR, C.B.E., Q.C., M.A., LL.B.
PROFESSOR R. M. BARRER, D.Sc., Sc.D., F.R.I.C.
PROFESSOR E. W. H. CRUICKSHANK, M.D., D.Sc., M.R.C.P.,
F.R.S.E.

CONSULTING EDITORS

LORD BOYD ORR, Newton of Stracathro, Brechin, Angus.
SIR CHARLES J. MARTIN, Cambridge.

EDITORS

D. P. CUTHBERTSON, Rowett Research Institute, Aberdeen (*Chairman*).
H. CHICK, Lister Institute, London.
I. LEITCH, Commonwealth Bureau of Animal Nutrition, Aberdeen.
E. M. HUME, Lister Institute, London.
S. J. COWELL, University College Hospital Medical School, London.
J. A. B. SMITH, Hannah Dairy Research Institute, Kirkhill, Ayr.

OVERSEAS CORRESPONDENT

U.S.A. H. H. MITCHELL, University of Illinois.

All communications should be addressed to the Secretary, "NUTRITION ABSTRACTS AND REVIEWS,"
ROWETT INSTITUTE, BUCKSBURN, ABERDEENSHIRE, SCOTLAND.

The Executive Council of the Commonwealth Agricultural Bureaux is a signatory to the Fair Copying Declaration, details of which can be obtained from the Royal Society, Burlington House, London, W. 1.

REVIEW ARTICLE

	PAGE
Land Use and Development in Australia. C. G. STEPHENS	731

ABSTRACTS

	PAGE		PAGE
1. TECHNIQUE		Riboflavin	798
Chemical		Nicotinic Acid (Niacin)	801
APPARATUS	741	Vitamin B ₆ (Pyridoxine, Adermin)	802
ANALYTICAL METHODS		Pantothenic Acid	805
General	741	Biotin	806
Carbohydrate Constituents	742	p-Aminobenzoic Acid	807
Nitrogenous "	744	Folic Acid (Pteroylglutamic Acid)	807
Lipoid "	747	Vitamin B ₁₂	811
Other Organic "	749	Other B Vitamins	819
Inorganic "	749	Vitamin C (Ascorbic Acid)	820
Hydrogen Ion Concentration	nil	Other Vitamins	825
Enzyme Activity	753		
Miscellaneous	754	4. PHYSIOLOGY OF NUTRITION	
Microbiological	756	Enzymes	825
Clinical and Experimental	756	Digestion and Absorption	827
Cooking, Sterilisation and Preservation of Food	762	Composition of Body Fluids and Tissues	
Culture of Micro-Organisms for Food	nil	BLOOD	830
		LYMPH, CEREBROSPINAL FLUID, ETC.	835
2. CHEMICAL COMPOSITION OF FOODSTUFFS		TISSUES	835
(except Vitamins, for which see Section 3)		Ductless Glands and Hormones	836
Energy Value, Proximate Principles and Inorganic Constituents		Energy Exchange and Specific Dynamic Action	839
GENERAL	767	Carbohydrates	844
FOODSTUFFS OF ANIMAL ORIGIN		Proteins and Protein Derivatives*	846
General	nil	Fats and other Lipids	857
Milk and Milk Products	768	Minerals	
Eggs	770	GENERAL	868
Meat (all kinds)	770	CALCIUM AND PHOSPHORUS	869
Fish	772	MAGNESIUM	871
Other Types	nil	SODIUM, POTASSIUM, AND SODIUM CHLORIDE	872
FOODSTUFFS OF VEGETABLE ORIGIN		HALOGENS	874
General	772	IRON AND COPPER	875
Cereals	772	OTHER MINERALS	877
Roots	nil	Acid Base Equilibrium	879
Leafy Vegetables	nil	Metabolism of Water	880
Legumes	nil	Metabolism of Other Substances	881
Fruits	775	Metabolism of Cells, Tissues, etc.	
Other Types	775	GENERAL PHYSIOLOGY	882
Pasture, Hay and Silage	775	GROWTH AND METABOLISM OF TUMOUR CELLS	884
MISCELLANEOUS	778	Metabolism of Growth, Reproduction and Senescence	
3. VITAMINS		GROWTH	884
General	778	REPRODUCTION AND LACTATION: MAMMALS	888
Vitamin A	779	" : BIRDS	892
" D	786	SENESCENCE	892
" E	787		
" K	790		
" B Complex: General	791		
" B ₁ (Aneurin, Thiamine)	794

AUTHOR INDEX

* Nomenclature of Amino-Acids

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

INTRODUCTION

DURING the years 1937 and 1938 a team of workers from the Rowett Research Institute made a dietary and clinical survey in selected areas of Great Britain. One of the present authors (A. M. Thomson) was a member of the clinical team. The aim of this survey (the Carnegie United Kingdom Dietary and Clinical Survey) was to record the diets of families with children and to assess the health of the children in terms of a number of clinical signs thought to be indicative of "state of nutrition"; finally the validity of these assessments was to be tested by a second clinical examination of a proportion of the children after their diets had been improved for about a year by the addition of foods to provide nutrients judged to be in poor supply. A comprehensive report on the Survey is now almost ready for press and will show that, apart from somatometric measurements, the clinical data have completely failed to throw light on one of the original questions, namely, what are the clinical signs of imperfect nutrition in a population of children not suffering from either starvation or outright deficiency disease. Nearly fifteen years have passed since

the Carnegie Survey was made, and the barrenness of the clinical results makes it desirable to review knowledge of procedures for appraising state of nutrition by clinical signs and laboratory tests. A first glance at recent pronouncements is not encouraging. The U.S. National Research Council (1949) says: "It is not easy to recognise early nutritional deficiency disease by simple inspection", and again: "... the interpretation of the findings with these [chemical] methods, with respect to the adequacy of nutrition, remains fraught with difficulty".

Yet it is important that we should seek for means of determining when and how health is likely to be impaired by imperfect diet, or improved by better diet. The whole concept of physiological food requirements depends on accurate assessment of health in relation to diet. Orr's (1937) definition of an optimum diet is in general, not physiological, terms: "a diet which will keep people in health; and the standard of health adopted is a state of well-being such that no improvement could be effected by a change in the diet". What are the criteria of this state of well-being, and what signs and symptoms arise when it is not attained? Throughout this review, we shall

bear in mind the *health* of individuals and of populations, in relation to diet. The mere fact that an individual or a population is consuming a diet which fails to reach some theoretical standard of "adequacy" is not necessarily evidence that health is impaired.

Concepts and Definitions

The terms "diet" and "nutrition", or "deficiency" and "malnutrition", are often used unsystematically and interchangeably, even during the course of the same report. Sometimes it is difficult to understand what is meant, because concepts seem to be as ill defined as terms. We could cite many examples, but a few quotations from the first volume of the Proceedings of the Nutrition Society will suffice to indicate the point of view which was common during the war years. Harris (1944) wrote that "partial deficiencies were the cause of definite ill-health, even in the absence of obvious clinical signs or symptoms". What is "partial deficiency", and what is the evidence of "definite ill-health" when clinical signs and symptoms are absent? One possible answer comes from a subsequent paper by Sinclair (1944) who said "The earliest changes in deficiency states are changes in function only, and are difficult to detect clinically until structural changes supervene". Following Sinclair, Platt (1944) also subscribes to the hypothesis—little or no concrete evidence is presented—that impairment of function should be distinguished from impairment of structure, but in terms of degree rather than duration of deficiency: "assessments of state of nutrition should be made at two levels, a low level at which clinical signs of dietary deficiency could be distinguished, and a high or optimal level. The test used to establish the attainment of the upper level should be designed to measure performance." So far, so good; but it may be noted that evidence of functional impairment is assumed tacitly not to be *clinical* evidence, a concept to which not everyone would subscribe. According to Yudkin (1944) "even if deficiency has been proved, it may be the effect rather than the cause of the condition". The obscurity of this statement is not wholly dispelled by his illustrative example of "deficiency of vitamin C in tuberculosis". How this deficiency was "proved" is not stated.

It seems desirable to state the meaning attached to terms in this review. *Nutrition* is an abstract term covering the whole process of taking and utilising food. "*State of nutrition*" or "*nutritional status*" is a convenient comprehensive term referring to health (level of well-being, in terms of growth, function and structure) in relation to food and its utilisation. Nutritional status may be

affected not only by quantity and quality of food eaten but also by anomalies in the utilisation of food, and the effects on health may be identical. Thus, for example, a low level of haemoglobin in the blood may be due to simple deficiency of iron in the diet, or to a multitude of other causes, from loss of blood to severe infection. Some of the more recent discoveries are difficult to fit into any simple theoretical scheme of types of nutritional status; for example, although sprue may respond to folic acid therapy (Spies, 1947; Cohen, Meyer and Fadem, 1952) it is not necessarily associated with deficiency of folic acid in the diet. Again, impairment of nutritional status may result from the *presence* in the diet of some prejudicial substance, e.g., the hypothetical substance in maize which may produce pellagra by inhibiting the action of nicotinic acid (Chick, 1951). It is not our intention to analyse and rationalise all the possible pathways whereby nutritional status may be altered. Pett (1950) gives a long list of these. Our concern is with the effects on nutritional status produced by insufficient or deficient diets. The clinical phenomena of insufficiency alone, i.e., simple underfeeding on a carefully balanced diet, have been described by Keys *et al.* (1950) and will not be discussed separately.

There seems to be no term which is generally agreed to refer specifically to "the effects on nutritional status produced by insufficient or deficient diets". Sinclair (1948) revived the obsolete word "nutriture", meaning "condition as to nourishment". He divides "health" into "nutriture" and "non-nutritional disease"; but does not include "structural defects not affecting health" due to "past malnutriture" under "health", so that the clinical signs of old rickets presumably have nothing to do with "nutriture". Earlier Dann and Darby (1945) used the word "nutriture", with acknowledgements to Sinclair, apparently quite interchangeably with "nutritional status". The introduction of the word seems to have done little except add to the confusion of an already confused terminology.

We think that the following series of definitions and concepts, though arbitrary, is at least simple and reasonably logical:

1. Well fed persons eating an *adequate diet* are in a *good state of nutrition*, provided the utilisation of food is not impaired.
2. Underfed persons eat an *insufficient diet* (insufficient in quantity) and develop the signs of *underfeeding*.
3. Malnourished persons eat a *deficient diet* (deficient in one nutrient or more) and develop the signs of *malnutrition*.
4. Signs of malnutrition or underfeeding follow, respectively, the taking of a deficient or

insufficient diet after a variable prodromal period, and some signs may persist if the diet again becomes adequate. We make no formal distinction between signs of present and past malnutrition. A knowledge of which signs indicate present, and which past, malnutrition is essential to the proper diagnosis of the current state of nutrition.

5. Evidence of underfeeding or malnutrition must be clinical, *i.e.*, impairment of growth, function or structure. On natural diets, underfeeding and malnutrition usually occur together.
6. Clinical signs identical with those of malnutrition may be produced by disease, metabolic abnormalities and other causes. The term "conditioned malnutrition" may be used to differentiate such types. This term is widely used. The equivalent term "conditioned underfeeding" would be appropriate for, say, *anorexia nervosa*.

The word "malnutrition", used in this way, needs further discussion. Severe degrees of malnutrition are usually labelled "deficiency disease". The term "latent (or subclinical) malnutrition" has been used to denote a state of health wherein no clinical defect is apparent even though the diet is believed to be deficient. It could be used to describe the prodromal phase of deficiency disease, but is usually employed with reference to a hypothetical stable state of impaired health between a good state of nutrition and deficiency disease. "Latent malnutrition" is thought to be detectable from the presence of a so-called "biochemical lesion", *i.e.*, a level of some nutrient or metabolite supposedly incompatible with continued good health, or a level believed to indicate low "nutritional reserves". Much confusion has been caused by validating such "biochemical lesions" in terms of concepts without any proven relationship with health, *e.g.*, "saturation of the tissues".

One more complication needs to be mentioned, and that is that the significance of clinical signs and symptoms may vary with the population under consideration. It is well known that body size, energy expenditure, atmospheric temperature and probably the presence or absence of endemic disease may influence requirements of energy or of nutrients, in respect of both the level at which reserves are stabilised and the intakes at which signs of underfeeding or malnutrition may arise. The general composition of the diet may affect the levels at which specific types of malnutrition become apparent. Even with so apparently simple a phenomenon as hunger (not chronic underfeeding or starvation) there may be great differences of significance. T. E. Lawrence (1935) wrote in "Seven Pillars of Wisdom": "The

assiduous food-habit of a lifetime had trained the English body to the pitch of producing a punctual nervous excitation in the upper belly at the fixed hour of each meal: and we sometimes gave the honoured name of hunger to this sign that our gut had cubic space for more stuff. Arab hunger was the cry of a long-empty labouring body fainting with weakness."

It should be noted particularly that the concept of dietary deficiency used throughout this review is associated with impairment of growth, function or structure, which impairment we call "malnutrition". The point is stressed because many authors use the term "deficiency" to connote either an intake below some arbitrary standard of adequacy or an intake which fails to meet the requirements of some arbitrary biochemical criterion. In neither instance is there necessarily any connection with health. We except metabolic studies showing continued negative balances from the category of "arbitrary biochemical criteria" since such balances must inevitably, in the long run, result in some impairment of growth, function or structure. In this review, we are restricting the term "malnutrition" to impairments associated with dietary deficiencies, although the Joint FAO/WHO Expert Committee on Nutrition (1951) says: "Malnutrition may . . . also result from excessive food intake".

A comprehensive review of the literature has not been attempted; references have been selected to illustrate the main facts and arguments.

CRITERIA OF SPECIFIC DEFICIENCY STATES

The Proximate Constituents

Little is known about possible specific effects of insufficiency of fat or carbohydrate in the diet. Since both take part in body structure and function, as well as contributing to the energy supply, simple inanition is not likely to be the only effect.

The only experimental trial of a diet providing less than 2 g. fat daily on a human adult was without demonstrable injurious effects over a period of 6 months. In fact, the subject was less prone to fatigue and ceased to suffer from migraine (Brown, Hansen, Burr and McQuarrie, 1938). Some inconclusive experiments on infants have been summarised by Sinclair (1952). A low carbohydrate intake in association with a high-fat diet would, of course, be expected to cause ketosis, but no recorded naturally occurring diet contains so much fat and so little carbohydrate and protein as to be ketogenic. The requirement of vitamin B₁ rises in proportion to the total amount of carbohydrate and protein to be metabolised, but, strictly speaking, excess of carbohydrate can exist only in relation to energy expenditure and obesity. Knowledge of human requirements of individual

fatty acids is fragmentary and unsatisfactory. Keys *et al.* (1950) recorded the appearance of dry and scaly skin, associated with follicular hyperkeratosis, during experimental underfeeding. This may possibly be due to removal of fat from the skin. As is noted below, subcutaneous fat is not removed in protein malnutrition.

The Joint FAO/WHO Expert Committee on Nutrition (1953) uses the term protein malnutrition "to indicate in general a state of ill-health occurring where diets are habitually poor in protein, while they are more adequate in calories. . . . The concept includes the effects of deficiency in the quantity of protein consumed, of imbalance of amino-acids, and deficiency of factors, such as vitamin B₁₂, commonly found in foods in association with animal protein and concerned with protein metabolism." Kwashiorkor, of which the chief cause is thought to be lack of protein, is described thus: "The main clinical features are failure of growth, retarded development, wasting of muscles, loss of appetite, mental apathy, oedema, dyspigmentation of hair and skin, diarrhoea, and the presence of undigested food in the stools. Subcutaneous fat is often well retained. There may be signs of associated vitamin deficiency. In the blood there is a reduction in the concentration of albumen and of certain enzymes." Post-mortem findings are: "fatty infiltration of the liver and atrophy of the pancreas and of other glands concerned with exocrine secretion, together with a diminution in the amount of pancreatic enzymes in the duodenal juice". See also Waterlow (1948) and Brock and Autret (1952).

Kwashiorkor may occur with energy deficiency of greater or less degree and it may be difficult to distinguish the signs of protein malnutrition from those of underfeeding, especially in severe cases. The levels of the plasma proteins appear to be insensitive indicators of protein malnutrition. In the Minnesota underfeeding experiment, there was no true reduction in plasma total protein or albumin. Keys *et al.* (1950) conclude that "the plasma protein level, as such, is of dubious merit in evaluating a person's nutritional status, at least in so far as that pertains to the protein stores in the body. A low plasma protein level, especially one in which the decrease is due primarily to a change in the albumin fraction, may indicate that the person has suffered from a dietary protein deficiency or an insufficient calorie intake. . . . There are, however, many normal persons in good nutritional status who may have protein levels comparable to those exhibited by semi-starved persons."

Experimental studies of single amino-acid deficiencies in man are in an early stage of development, and so far loss of weight among infants, associated with negative nitrogen balances, has been found to follow experimental deficiencies of

tryptophan, isoleucine, lysine and sulphur amino-acids lasting for 7 to 10 days (Albanese, 1952). In healthy young men deprived of valine for 4 days or of methionine for 6 days there were "profound failure in appetite, a sensation of extreme fatigue, and a marked increase in nervous irritability" (Rose, Johnson and Haines, 1950). It is not known whether such specific amino-acid deficiencies arise with natural dietaries, but this seems on the whole unlikely, unless perhaps where deficiency of tryptophan may arise on a predominantly maize diet and help to precipitate pellagra.

In general, then, it would appear that specific malnutrition due to shortage of fat or carbohydrate has not been described and the only specific consequence of protein deficiency known to exist is outright deficiency disease. Combined deficiencies of the proximate constituents of diet do, of course, produce underfeeding and such non-specific effects as impairment of growth.

Calcium, Phosphorus and Vitamin D

It is convenient to consider these three nutrients together. The deficiency diseases with which they are associated are rickets and osteomalacia.

The British Paediatric Association (1944) said that "most observers are agreed that the severe type of rickets with deforming bone changes has almost disappeared from Great Britain and with this disappearance the clinical conception of rickets must undergo some modification", which suggests that the old name is being transferred to less severe and perhaps even different conditions. The Association, in war time, studied "essentially healthy children in whom ricketty changes were likely to be minimum rather than maximum". Most of the children were aged under 2 years. The Report concludes that "in the severe types the clinical diagnosis of rickets is usually easy, in the milder forms extremely difficult and in the minor degrees of bony change quite impossible".

Radiological methods of diagnosis are not much better. In the survey cited above, "the correlation between the clinical and radiological diagnosis was very poor in Great Britain where only a small proportion of the clinically positive cases were confirmed radiologically", whereas "clinical methods of diagnosis failed to pick out half of the cases of active rickets diagnosed by radiology". These discrepancies might be dismissed on the basis that deformities may persist after healing and that it is impossible, except by radiography, to detect slight deformity of an epiphyseal line, but the table which details the findings of the radiologists who reported independently on the same films shows that there was considerable disagreement between them. This may be a matter of interpretation. Jeans (1936) showed that rickets

may be diagnosed, on the basis of X-ray films, in babies having abundant vitamin D and high retentions of calcium and phosphorus where the changes are "merely concomitants of rapid normal growth". Or it may be the more general question of observer error from which radiologists in other fields are not immune (*Lancet*, 1954).

Radiological observation of ossification pattern has been used in the study of disturbances of ossification. Schmid (1949), working in Germany, found that rickets now causes delay of ossification only in a minority of infants. Part of the variability in rates of ossification may be associated with variation in growth and development generally, *i.e.*, may be a general rather than a specific characteristic of malnutrition. This aspect will be dealt with later (p. 14).

The observation that serum alkaline phosphatase increases early in rickets and parallels the activity of the disease and the healing process gave hope that estimation of the enzyme would be of value for diagnosing minor deficiency states, especially in young children among whom other causes of a rise are less usual. According to the U.S. National Research Council (1949), "The value of including phosphatase determination in surveys other than those involving infants and young children remains to be determined", but even in young children and infants it must remain in doubt until early rickets has been better defined in radiological and clinical terms.

There is no change in blood serum calcium characteristic of rickets and, although serum inorganic phosphorus appears to be consistently low in untreated rickets, it may not respond to treatment, or it may respond rapidly and remain normal whether healing progresses or not (Medical Research Council, 1932; Bodansky and Jaffe, 1934). Therefore its practical value in diagnosis is doubtful.

Accounts of hunger osteomalacia in central Europe after the first World War and of osteomalacia associated with such abnormal social customs as *purdah* in the Far East (Medical Research Council, 1932), the one attributed to acute and the other to chronic deficiency of calcium and vitamin D, do not throw any light on the early diagnosis of mild deficiencies in more normal circumstances. The same may be said of Danish accounts of severe osteoporosis with pain and deformity, described by Meulengracht and Meyer (1937) and Meulengracht (1939) as due to poor diet in subjects with or without achylia, or to abuse of laxatives. The study of Owen, Irving and Lyall (1940), which showed the existence of generalised osteoporosis without sign or symptom in old men on poor diets, also showed that calcium and phosphorus equilibrium could exist on low intakes with the extremely low reserves indicated by osteoporotic bone. Hence even metabolism gave no

indicative evidence of deficiency and only deliberate search and radiography could provide a diagnosis.

Bernard (1952) has found contraction and flattening of the pelvic brim in both men and women of short stature, especially those in poor general health and from a poor social background. This contracted pelvis is associated, among women, with a high incidence of difficult labour due to disproportion, and may be regarded as a deformity of sub-rachitic type. The age at which the contraction occurs is not known.

Research on the structure, composition and health of teeth goes on continuously and we make little progress towards relating the epidemiology of dental caries in man to his general health or his diet. The caries experience of the healthy public school boy is in no respect different from that of the average council school boy (Carnegie Survey) and all that distinguishes them is the extent and quality of dental care. There are strange local differences in the structure and health of teeth, differences which have every appearance of being related to diet; but it is not only one diet or one type of diet that is associated with good teeth, and the presence of excellent teeth is by no means always associated, in either racial groups or individuals in one group, with good health. Indeed, the only concrete evidence on any considerable scale of simultaneous improvement of general health and reduction of dental caries comes from the experience of the recent war (Bransby and Knowles, 1949; Toverud, 1949). It is sometimes thought that the diminution in caries experience may have been related to sugar rationing. For diagnosis of malnutrition or of state of health, the degree of caries experience is of no help whatever.

Iron

It is generally accepted that deficiency of iron in the diet can produce hypochromic anaemia, but there is more doubt about the value of measurement of haemoglobin level as an index of the nutritional status of populations. The Carnegie Survey failed to show any differences in average haemoglobin level among children in different food expenditure groups; the data as a whole agreed very well with those of the survey of haemoglobin levels among schoolchildren in 1943 by the Medical Research Council Committee on Haemoglobin Surveys (1945), when, presumably, nutritional levels were if anything higher than in 1937-1938. The authors of the Medical Research Council report make no general conclusion on the existence or interpretation of differences in haemoglobin levels between different economic groups. Instead they emphasise the technical difficulties of obtaining reliable values even with a team of experts who had been subjected to a test

of accuracy and who used calibrated apparatus. It seems clear that a haemoglobin survey is by no means a light undertaking and that results will not reflect sensitively such differences in diet as may exist among a population like that of Great Britain.

The U.S. National Research Council bulletin (1949) says that "Determination of serum iron should prove to be a most useful procedure in the assessment of nutritional status". On the other hand, it also notes that "Low serum iron is not pathognomonic of iron deficiency".

Vitamin A

It is well known that vitamin A goes through the vitamin A-rhodopsin-retinene-vitamin A cycle during the adaptation of the retina to darkness and to light. According to Wolbach and Bessey (1942), characteristic changes of the epithelium occur in vitamin A deficiency, namely, keratinising metaplasia in the salivary glands, the respiratory tract, the genito-urinary tract, the eyes, and (in man) the skin and hair follicles. The role of vitamin A in dark adaptation fits the observation that clinical night blindness, curable by vitamin A, may occur among severely depleted populations; it has been held also that characteristic hyperkeratotic lesions of the skin and hair follicles may occur in severe and long-continued vitamin A deficiency (Frazier and Hu, 1931; Nicholls, 1935).

The Medical Research Council (1949) reported on an investigation in which 16 deprived and 7 other volunteers subsisted for not less than 6½ months on a daily diet providing less than 500 I.U. of carotenoids. The latter received carotene supplements. Eleven of the volunteers, 9 in the deprived group and 2 others, took the diet for from 20 to 25 months. Two of the deprived subjects thought that they became slightly night blind. These two and one who did not complain of clinical night blindness showed raised rod thresholds, but "only one of the three subjects showing a raised threshold with the Wald instrument gave abnormal readings with the Craik adaptometer". Suggestions are made (p. 47) about possible reasons for this difference. Whether the explanation lies in the techniques used or in the subjects' use of "the most efficient part of the retina", the fact remains that they had already been on a diet almost free from vitamin A for 10, 12 and 20 months when the first deviation from normal was found.

Rod scotometry showed that "two of the subjects whose final rod threshold was definitely raised showed also grossly abnormal fields of vision. In some subjects abnormal fields of vision seemed to be the only feature associated with vitamin A deficiency."

Clinical examination was equally unrewarding. "The great majority of clinical examinations

revealed no significant differences between the deprived and non-deprived group, or in the same person before and after deprivation of vitamin A. This applied to the biomicroscopical appearance of the cornea and conjunctiva, the blood picture including platelet counts, gastro-intestinal abnormalities, and the incidence of colds and coughs. The only signs and symptoms which seemed to be commoner in the deprived group, though their significance was doubtful, were dryness of the skin and eye discomfort. Audiometry, however, showed a significant worsening of hearing in the deprived group. In several of the subjects follicular hyperkeratosis was present at the start and varied during the experiment, but the variations bore no relation to the vitamin A intake." It is of interest that the clinical and histological characteristics of the hyperkeratosis were similar to those of the condition found in starvation by Keys *et al.* (1950) and in experimental vitamin C deficiency by the Medical Research Council (1953). In the vitamin A deficiency experiment, estimations of blood carotenoid content showed an average fall from 150 I.U. to about 40 I.U. per 100 ml. within 3 months, most of the residual carotenoid content consisting of substances other than α - and β -carotene. "No other effect which could definitely be ascribed to the deficient diet occurred during the first eight months." The average plasma value for vitamin A of the deprived group during the first 2 months on the diet was 88 I.U. per 100 ml. (a "normal" value of about 120 I.U. is proposed, on the basis of other data); after about 8 months "a definite downward trend was shown in ten out of the sixteen volunteers in the group. The fall became very pronounced in four men who eventually reached levels below 50 I.U. vitamin A per 100 ml. . . . One man, however, showed no appreciable drop even after twenty-two months of deprivation."

Thomson *et al.* (1939) had earlier investigated the use of dark adaptation in evaluating the nutritional status of British schoolchildren in respect of vitamin A. Using a specially designed adaptometer and a technique which yielded reproducible results on subjects irrespective of previous exposure to light, they found no relationship between the time taken to reach the rod threshold and the vitamin A content of the family diet. A few subjects with impaired dark adaptation were found and studied; their condition was not caused by dietary deficiency of vitamin A, but was cured by injecting large doses of the vitamin intramuscularly and was presumably due to some metabolic abnormality. The Medical Research Council volunteer experiment indicates that these findings were reliable, and it is noteworthy that tests of dark adaptation seem now to have fallen out of use in surveys of nutritional status.

Follicular hyperkeratosis likewise seems to have little or no value as an indication of vitamin A deficiency (Stannus, 1945). The Medical Research Council's experiment suggests that the same is true for eye signs, such as xerophthalmia. Kruse (1941) claimed that biomicroscopical examination of the conjunctiva is a sensitive method of determining the existence of slight or early vitamin A deficiency, but this is not borne out by the experimental work referred to above. In the report of the Medical Research Council experiments, it is stated that the buccal cavity was examined, but no results are given. There seems to be little information on human mucous membranes in vitamin A deficiency. Gerrie (1944) reported that nasal sinusitis among Aberdeen children was found to be associated with metaplasia of the epithelium in a small percentage of cases, and that oral or parenteral vitamin A treatment reduced the proportion going on to the suppurative stage. It is not known whether these cases were associated with any marked dietary deficiency of vitamin A, but this is unlikely.

Estimations of vitamin A and carotene levels in blood appear to yield little exact information. As the Medical Research Council experiment showed, subsistence on a diet containing minimum amounts of carotenoids and almost no preformed vitamin A resulted in a fairly rapid (2 to 3 months) fall to about 40 I.U. per 100 ml. in the plasma carotenoid levels, and a more erratic and less marked fall in plasma vitamin A. The U.S. National Research Council (1949) said "It seems apparent that there is a relationship between the amount of vitamin A and carotene in the blood and clinical evidence of vitamin A deficiency, but wide individual variations occur and a given level should be interpreted with caution. . . . In summary, a low level of vitamin A in the blood may mean vitamin A deficiency, decreased reserve stores, or the presence of some disease which affects vitamin A metabolism . . . low levels suggest deficiency but should be correlated with other findings for definite diagnosis." As already shown, these "other findings" themselves present no small difficulty of interpretation.

Vitamin B Complex

The members of the vitamin B complex have many roles in connection with the enzymes and co-enzymes governing the oxidation-reduction processes of intracellular metabolism. To what extent their functions may overlap or supplement one another is by no means clear, but meantime it seems possible that the role of each vitamin is not wholly peculiar to itself and independent of the roles of all the others. To relate the known biochemical functions of any given vitamin to its effect on physiological processes and on health is

as yet difficult because, as Peters pointed out in 1946, "chemistry and biochemistry have rushed ahead lately and . . . true nutritional work takes rather longer to do, because it involves physiology". The requirements of B vitamins are thought to be related to metabolism of carbohydrate, and this is certainly true of vitamin B₁, so that its requirement rises with the non-fat calories of the diet, and deficiency tends to be more common when energy expenditure is high.

Vitamin B₁

The classical deficiency disease is beriberi, which was recently experienced by many European prisoners of war in Japanese prison camps. Smith (1946) reported that in Hong Kong "there was nothing unusual about the clinical picture of these cases, in which there was oedema with the neurological manifestations, except that serious cardiac involvement was not common. The onset followed acute bacillary dysentery in 55 per cent. of the dysentery cases." The disease was controlled by the administration of 3 mg. crystalline vitamin B₁ every other day, and the response of established cases to treatment with the synthetic vitamin was "uniformly satisfactory". Burgess (1946) showed that the occurrence of beriberi in Singapore was related to the vitamin B₁ content of the diet. "In the first three years vitamin B₁ deficiency manifested itself in the form of oedematous, cardiac, and neuritic beriberi and as Wernicke's encephalopathy." It "appeared in about six weeks on a daily intake of 0.2 mg. per 1000 non-fat Calories (N.F.C.) or a total intake of 0.39 mg., and fresh cases ceased to occur when the daily intake rose to 0.5 mg. per 1000 N.F.C. or a total of 1.2 mg.". Cruickshank (1946) gives the following criteria for the diagnosis of vitamin B₁ deficiency:

- (1) Neurological manifestations
 - (a) Definite subjective and objective sensory changes;
 - (b) Muscular weakness and aching, with reflexes markedly diminished or absent;
 - (c) Wernicke's encephalopathy, *i.e.*, vomiting associated with nystagmus, paralysis of the external muscles of the eye and mental confusion.
- (2) Cardiovascular manifestations
 - (a) Oedema which cannot be attributed to nephritis, valvular disease of the heart, venous obstruction, or protein deficiency;
 - (b) Tachycardia with cardiac enlargement, alterations in the heart sounds and the appearance of murmurs without obvious cause.

"A diagnosis of vitamin B₁ deficiency was made if the findings fell under any one of the above subheadings. Usually, however, more than one of these signs were present in a given case."

Williams and others (1940 ; 1942 ; 1943) recorded the effects of experimental vitamin B₁ deficiency among human subjects. In their three experiments intake varied from 0.15 mg. to 0.45 mg. daily. The symptomatology was, on the whole, quite unspecific. In the first experiment, involving the most severe deficiency, "the abnormalities ultimately noted in all of the subjects who were deprived of thiamine for periods of several weeks were : depressed mental states, generalised weakness, dizziness, backache, soreness of muscles, palpitation, dyspnea and precordial distress (pseudo-angina) on exertion, insomnia, anorexia, nausea, vomiting, loss of weight, atony of muscles, very slight roughness of the skin, faint heart sounds, lowered blood pressure and bradycardia when at rest, with tachycardia and sinus arrhythmia on exertion. In all cases physical activity greatly decreased. Less regularly there were observed states of apathy, reawakening of psychotic trends [the subjects were, it appears, "recovered" mental patients], difficulty of thought and memory, photophobia, headache, abdominal distension, sensations of cold and heat, burning of the soles of the feet, numbness of the legs, fatigue of the ocular muscles, tenderness of the muscles of the calves and depressed tendon reflexes." All signs and symptoms disappeared when the pure vitamin was administered. It may be noted that the experiment did not include an independent control series. The clinical insignia, which are described as those of "true neurasthenia" progressing to *anorexia nervosa*, are obviously of little value in diagnosing early vitamin B₁ deficiency ; the authors (1940) note that "another conclusion suggested by our observation is that the isolated withdrawal of thiamine does not produce beriberi".

In the 1943 experiment of Williams *et al.*, the amount of vitamin B₁ excreted with and without a test dose of the vitamin decreased steadily during the experiment (intake 0.2 mg. daily for 120 days, with a test dose of 1.0 mg. about every second week) while the concentration in the blood of glucose, and of lactic and pyruvic acid after glucose administration, increased, these last changes beginning to show about the 50th day. The U.S. National Research Council (1949), reviewing the literature, found excretion of vitamin B₁ in the urine, with or without a test dose, to be of doubtful value in assessing nutritional status. "Pyruvic acid determinations during fasting, after glucose, or after exercise are useful in evaluating thiamine nutrition, particularly in individuals. These methods require considerable care, are time-consuming, and are not readily applicable to surveys. Furthermore, many pathological conditions other than thiamine deficiency are associated with a rise in pyruvic acid in the blood." It seems fair to conclude that no biochemical method of assessing

vitamin B₁ deficiency has yet attained any degree of reliability or specificity.

Riboflavin

No clinical state attributed to riboflavin deficiency was described before the demonstration by Sebrell and Butler (1938) that 10 out of the 18 women maintained for 94 to 130 days on a diet of cornmeal, cowpeas, lard, casein, flour, white bread, chalk, cod liver oil and tomato juice, with supplements of iron and vitamins B₁ and C, developed a lesion of the lips which was called "cheilosis". It was cured by pure riboflavin. That the diet used did not produce a pure riboflavin deficiency is shown by the fact that one subject developed pellagra and was cured by nicotinic acid. Soon afterwards (Oden, Oden and Sebrell, 1939) 3 women were found in rural Georgia with lesions similar to those which appeared in the trial, and they were cured by riboflavin. Ten years later Horwitt and colleagues (Horwitt *et al.*, 1948, 1949 ; Hills *et al.*, 1951) made a controlled trial of experimental riboflavin deficiency on 15 men ; the experimental diet contained 0.55 mg. of the vitamin and was judged to be complete in other respects. After 4½ months the subjects developed changes in the skin, including patchy seborrhoea of the scalp and chest, scrotal dermatitis, angular stomatitis, cheilosis and fissuring of the *alae nasi*. Scrotal dermatitis was the commonest lesion and with one exception responded, like the other skin lesions, to the administration of riboflavin. No circumcorneal injection, vascularisation of the cornea, or tongue change was seen.

Riboflavin deficiency has frequently been observed in the field since Oden, Oden and Sebrell's original case reports. Skin lesions are usually noted, but glossitis is usual also. For example, Hou (1944) describes characteristic patches of bluish-red or magenta discolouration with flattened, or scattered prominent, papillae. Jones *et al.* (1944) described an outbreak of stomatitis among men of mixed race in a camp in North Africa, subsisting on a diet containing about 1.0 mg. riboflavin daily ; the stomatitis was curable by Marmite or riboflavin. Thomson and Freedman (1947) described a similar outbreak among Indian troops. The presenting symptoms were sore throat, hoarseness and dysphagia, and on examination all cases were found to have a characteristic glossitis, in which stripping of the fur and epithelium occurred at the edges and tip of the tongue, leaving smooth, dark red or magenta areas ; in a later stage stripping of the epithelium was complete. Variable proportions of the men examined showed fissuring of the tongue, rhinitis, cheilosis, angular stomatitis, macroscopic "vascularity" of the cornea, maceration of the buccal

mucous membrane, and proctitis. Only one was found with scrotal dermatitis. All signs and symptoms cleared on treatment with yeast or pure riboflavin. That mental changes occur in riboflavin deficiency is shown by the following passage: "The men were somewhat depressed, apathetic and lethargic . . . from the unit officers' point of view the situation was readily accounted for by 'staleness' and they saw no cause for alarm. . . . Among these men, treated with riboflavin or yeast, a remarkable improvement in mental condition was evident, which was all the more noticeable by contrast with those in other [control] groups, who remained listless and morose." Jones *et al.* (1944) say of their subjects: "As early as the second day [of treatment] they became full of thanks, which is the more remarkable because these people are usually grudging in their gratitude".

Thomson and Freedman (1947) suggest that the rather variable clinical picture of riboflavin deficiency may be explained in terms of a "wear and tear mechanism". "The tongue, lips, buccal mucous membrane, soft palate, pharynx and epiglottis, nose, anus and lower rectum and scrotal skin (and, perhaps, the eyes) all have one feature in common—the epithelium is exposed to a relatively greater degree of wear and tear than other epithelial surfaces. Under normal conditions, regeneration keeps pace with wear and tear. In riboflavin deficiency, interference with cell metabolism impedes epithelial regeneration, and failure to keep pace with destruction occurs first at those sites where wear and tear are greatest. Individual differences of wear and tear may, perhaps, explain variations in symptomatology from case to case."

Biomicroscopical examination of the corneal limbus has had a vogue as a diagnostic method in mild or early riboflavin deficiency. Bessey and Wolbach (1939) found vascularisation of the cornea as an early sign of riboflavin deficiency in the rat, and Kruse *et al.* (1940) reported human keratitis responding to riboflavin therapy. Tisdall, McCreary, and Pierce (1942) reported that marked vascularisation of the cornea was found in Canadian aircrews and disappeared when large doses of riboflavin were given, but they later modified their conclusions (McCreary, Nicholls and Tisdall, 1944). About the same time Sandstead (1942) questioned whether superficial vascularisation of the cornea can be used as a diagnostic sign of riboflavin deficiency, but Stern, in 1950, thought the reverse, provided the deficiency was long-standing. The position is therefore somewhat confused but, in general, it seems true to say that this method of diagnosis has fallen out of favour.

There is no doubt that the signs and symptoms of riboflavin deficiency can arise in persons whose diet is adequate. Machella and McDonald (1943) have reported a series of "typical" cases which

failed to respond to synthetic riboflavin; some improved on treatment with brewer's yeast or other components of the vitamin B complex. One of the present authors (A. M. Thomson) has seen typical mouth signs in individual Indian soldiers persist despite long subsistence on an adequate diet with liberal supplements of milk.

Biochemical methods of assessing riboflavin deficiency have been widely studied, but few have related measurements to clinical condition. During experimental deficiency, urinary excretion of riboflavin falls, but there is considerable disagreement on the biochemical findings which indicate deficiency, and whether fasting excretion or load tests yield the more informative results (U.S. National Research Council, 1949).

Nicotinic Acid

Neither experimental production of pellagra nor field observation has yielded criteria by which the preliminary stages of deficiency may be identified.

Goldsmith *et al.* (1952) gave seven women suffering from psychoneurosis a diet low in vitamin B complex and supplemented by pure vitamins except nicotinic acid. The diet contained about 7.0 g. nitrogen, 4.7 mg. nicotinic acid, and 190 mg. tryptophan. No clinical sign of nicotinic acid deficiency was seen in two subjects who received the diet for 42 days, but clinical signs of pellagra developed between the 50th and 60th day in three who consumed the diet for 81, 117 and 135 days in all. The signs included mental depression, dermatitis, diarrhoea and inflamed tongue. Angular stomatitis appeared in two of the subjects who were receiving about 2 mg. riboflavin daily. Treatment with 30 mg. daily of nicotinamide in the diet was followed by subjective improvement within 24 to 48 hours; one month was required for complete healing of the dermatitis.

Sydenstricker (1941), writing with a wide knowledge of pellagra as seen in the Southern States of America, said: "In the chronic partial deficiency of B vitamins which finally results in the syndrome of pellagra, the symptoms and signs of nicotinic acid deprivation are prominent. Mild psychic disorders may precede other manifestations by weeks or months. Neurasthenic complaints of all sorts are common. Slight mental retardation, loss of memory for recent events, apprehension, confabulation, depression or mild delusional states may recur for months or years. Partial deafness, particularly for high pitched tones, may be the presenting symptom. Digestive disturbances, particularly gastric discomfort after meals, burning of the esophagus and stomach, flatulence and constipation are almost invariable, anorexia is very apt to develop, with decreased intake of all sorts of food. Soreness of the tongue, often with no visible

glossitis, is a common complaint. In women there is apt to be a concurrent non-specific vaginitis, usually with hyperesthesia and dyspareunia." None of these signs and symptoms is specific.

Kruse (1942) described lesions of the tongue discernible with the biomicroscope, which he claimed to be diagnostic of the earliest stages of nicotinic acid deficiency. They showed some evidence of slow healing when heavy doses of nicotinic acid were given by mouth, but the process was often incomplete after 14 months of treatment.

A confusing literature on the excretion of nicotinic acid and its derivatives led the U.S. National Research Council (1949) to conclude that "findings should be interpreted with caution in evaluating niacin nutrition".

Other Aspects of Vitamin B Complex Deficiency

Very little is known about human dietary requirements, if any, of other components of the vitamin B complex, and still less about the possible clinical insignia of deficiency. The situation is made difficult, from the experimental point of view, by synthesis of these nutrients in the intestine. Conditioned deficiency of vitamin B₆ was produced in 34 of 50 subjects by administration of the antimetabolite deoxyypyridoxine (Vilter *et al.*, 1953). They found that "vitamin B₆ deficiency in human beings mimics the clinical manifestations of all vitamin B complex deficiency states", with seborrhoeic dermatitis, glossitis, cheilosis, conjunctivitis, peripheral neuritis, anorexia and lethargy. A diet in which 30 per cent. of the energy was derived from egg white was used to produce biotin deficiency in man (Sydenstricker *et al.*, 1942). Such experiments cannot be regarded as necessarily having a relation to any naturally occurring deficiency disease, and there is no evidence of such naturally occurring deficiencies of other components except possibly vitamin B₁₂. The relationship between vitamin B₁₂ and animal protein makes it possible that deficiency of vitamin B₁₂ does occur in and affect the course of kwashiorkor, tropical macrocytic anaemia and macrocytic anaemia of pregnancy.

Outside the laboratory, deficiencies are seldom or never simple and in field observations lack of the vitamin B complex may be confused by the simultaneous presence of infectious disease or disturbances of intestinal function. Such considerations may account for the remarkably varied clinical pictures produced among prisoners of war in Japanese internment camps, where, in addition to beriberi, pellagroid conditions, and riboflavin-deficiency states, unexpected conditions such as "burning feet" and retrobulbar neuritis were common. Deficiency states clinically resembling those attributed to members of the vitamin B

complex were frequently seen among troops in India, particularly on the Burma front. Among British troops, sprue-like syndromes were usual, while among Indian troops severe macrocytic anaemia and "marasmus", associated with diets containing little meat, were common. Marriott (1945), Girdwood (1948), Keele and Bound (1946) and Thomson (1946), have described the clinical manifestations, which arose without warning in the Indian troops who were not particularly anaemic beforehand but were exposed to heavy malarial attack. British troops, similarly infected, responded satisfactorily to conventional treatment, but the Indians frequently did not respond to malarial or anti-anaemic treatment. It seems clear that these were "conditioned" deficiency states rather than the results of simple deficiencies in the diets.

Horwitt *et al.* (1948) studied a group of five men aged between 20 and 40 and seven aged between 60 and 80 (mental patients) who for 3 years received a mixed diet supplying 2000 Cal. and about 400 µg. vitamin B₁ and 800 µg. riboflavin daily. A similar group received the same diet supplemented with yeast extract for 2 years, then a diet with about the same riboflavin content and a vitamin B₁ content of 200 µg. A control group received normal hospital diet. "No definite claim of changes could be made in the first year of the experiments." Later there were changes in the skin, which became thin and smooth with decreased turgor. Changes in the lips included dryness, erosions and detachment of the epithelium at the edge. There was some impairment of appetite, reduced blood pressure and slight oedema in the older subjects. Severe restriction of vitamin B complex brought about correspondingly severe physical and mental changes, including oedema and lowered blood pressure, loss of appetite with gastro-intestinal disturbances, and neuropathy and affections of the skin. The results suggested that the young were less resistant than the old.

It may be noted, in passing, that in almost all the experimental studies of vitamin B deficiency states great emphasis is laid on mental changes. This emphasis is much less clear-cut in field observations, except of pellagra. As was already noted, Thomson and Freedman's observations during an outbreak of riboflavin deficiency made the point that mental impairment became obvious only by the contrast between "cured" and untreated cases. Descriptions of mental disturbances are conspicuously uncommon among accounts of deficiency states in Japanese prisoner-of-war camps. It may be that the conditions of experiments in mental institutions tend to magnify effects on personality, especially when physical changes are of slow onset and relatively undramatic quality.

Vitamin C

The experiment of Crandon, Lund and Dill (1940) was the first in which voluntary deprivation was maintained until clinical signs appeared. The first symptom of deficiency was extreme fatigue after about 3 months. The earliest sign was follicular hyperkeratosis after 132 days, followed by the perifollicular haemorrhages characteristic of scurvy. No gross change in the gums was observed. There was unsatisfactory healing of an experimental wound. A more extensive trial of experimental vitamin C deficiency is that of the Medical Research Council (1953) undertaken on 20 subjects of whom 10 were completely deprived, three were given 70 mg., and seven were given 10 mg. vitamin C daily in addition to the experimental ascorbic-acid-free diet. The first sign of deficiency was follicular hyperkeratosis, appearing after from 21 to 26 weeks. A few weeks later, haemorrhagic changes in the hair follicles appeared and progressed. Gum changes appeared after at least 23 weeks of deprivation, beginning with reddening, swelling and tiny haemorrhages in the tips of the interdental papillae. After 9 months, nine out of the ten subjects showed gum changes, which in 2 were gross, the gums being purplish, much swollen and spongy. Experimental wounds were made in 6 of the 10 subjects after from 4 to 8 months' deprivation. The wounds healed normally, but later there were haemorrhages into the scar tissue. New wounds made at the stage of pronounced scurvy failed to heal at the normal rate. "Special incidents" caused emergency curtailment of the experiment in some cases. One volunteer developed knee-joint effusions, and 2 others signs of cardiac failure. There was no psychiatric disturbance. Agility tests indicated increased fatigue, but exercise tolerance tests failed to show any significant difference of pulse-rate response among the 3 main groups of volunteers. Tests of capillary strength, both positive and negative, failed to reveal any change. There were no significant haematological changes. Pains in the back, joints and limbs were reported with increasing frequency as the signs of scurvy developed.

This picture is clearly similar to, if not as horrifying as, that of scurvy experienced by the old seafarers. In "The Voyages of Jacques Cartier" during the 16th century (Biggar, 1924) we read: "The sickness broke out among us accompanied by most marvellous and extraordinary symptoms; for some lost all their strength, their legs became swollen and inflamed, while the sinewes contracted and turned as black as coal. In other cases the legs were found blotched with purple-coloured blood. Then the disease would mount to the hips, thighs, shoulders, arms and

neck. And all their mouths so tainted, that the gums rotted away down to the roots of the teeth, which nearly all fell out."

Neither the experimental nor the field observations offer any means of diagnosing incipient scurvy. The earliest signs are non-specific. Parry (1821) says "... and one day in the week was appointed for the examination of the men's shins and gums by the medical gentlemen, in order that any slight appearance of the scurvy might at once be detected, and checked by timely and adequate means". It is doubtful if modern "medical gentlemen", relying on clinical observation alone, could do anything more.

As regards laboratory methods, Crandon found that his plasma ascorbic acid fell to zero within 2 months (two months before the appearance of the first clinical sign), and ascorbic acid in the white cells of the blood fell to zero after 122 days, *i.e.*, about 2 weeks before the appearance of perifollicular haemorrhages (Crandon, Lund and Dill, 1940). In the Medical Research Council experiment, the plasma level was 0.55 mg. per 100 ml. during a preliminary period when 70 mg. ascorbic acid were being given, and fell to 0.03 mg. after 37 days of deficiency. The position was similar among the volunteers receiving 10 mg. daily. Levels in the white blood cells fell from 15.6 mg. per 100 g. during the preliminary period to 1 mg. in 113 days, and remained below that value for the remainder of the experiment. Among the volunteers receiving 10 mg. vitamin C the white cell level fell to between 1.5 and 3 mg. per 100 g. in 86 days and remained at about 1 mg. from about the 109th day onwards. "About 100 days elapsed between the virtual disappearance of vitamin C from the plasma and the appearance of the first clinical signs of scurvy. On the other hand, the concentration of vitamin C in the white cells reached its lowest value only 3 to 6 weeks before clinical scurvy appeared." It is of interest that the plasma and white cell levels could scarcely distinguish between volunteers almost totally deprived and those receiving 10 mg. ascorbic acid daily. "It is doubtful whether a single blood determination could differentiate the concentration of vitamin C in plasma, whole blood or white cells of persons on a prolonged intake of about 1 mg., which in nine cases out of ten produced scorbutic haemorrhages after 6 to 8 months, from that of persons on an intake of about 11 mg., which over a period of 14 months prevented the appearance of the clinical signs of scurvy. . . . For assessing the state of vitamin C nutrition it appears that, in a fasting person, a plasma value below 0.10 mg. per 100 ml. indicates an average daily intake of 20 mg. or less. If, therefore, in a doubtful case of scurvy the plasma level is 0.10 mg. per 100 ml. or more, the existence of scurvy is

very improbable, since the intake of 20 mg. daily, necessary to maintain a plasma level of 0.10 mg. per 100 ml., was found to be an adequate curative dose. On the other hand, a plasma level of below 0.10 mg. per 100 ml., though an accompaniment of scurvy, is not proof of scurvy or of imminent scurvy. . . . The determination of vitamin C in the white cells is of somewhat greater diagnostic value, because it shows more definite differences between the daily intakes of 20 mg., 10 mg., and less than 5 mg. A concentration below 2 mg. per 100 g., especially when confirmed on repeated analyses, indicates severe depletion and supports the diagnosis of scurvy. Eventually, with some further improvement in the technique, it may be possible to assess the dietary intake from the result of vitamin C estimations on the white cells." On the basis of these experiments, there is no evidence of any impairment of health at levels of vitamin C intake not producing scurvy and, indeed, there is no satisfactory evidence of "latent malnutrition" in respect of vitamin C elsewhere in the literature.

THE DIAGNOSIS OF MALNUTRITION

Naturally occurring "malnutrition" is seldom, if ever, the result of a single deficiency and may be regarded as the sum of several specific and separate deficiency states or as a general reaction to a multiplicity of causes. As the preceding section of this review has shown, it is in practice impossible to recognise any specific deficiency before the appearance of characteristic signs; such early reactions as appear are non-specific. For these reasons, a general concept of non-specific "malnutrition" is valid and useful, and may be defined as those defects of growth, function and structure which are produced by deficient diets of many kinds and which may be accompanied by some degree of underfeeding. In practice, insufficiency and deficiency tend to occur together.

The Clinical Picture

The observant physician knows that he can, in general, distinguish between the appearance of good health and poor health although, if he is critical, he knows also that his judgment is subject to a high degree of "observer error", probably dependent in large measure on the standard of health among the population to which he is accustomed. Thomson (1945) attempted to delineate the characteristics of good and poor health, from the nutritional point of view, among soldiers:

"The well-nourished soldier . . . has been well-nourished and active from infancy, and generally comes of well-nourished stock. He has suffered no disease which has left any permanent dis-

ability. In stature and build he is usually (though not necessarily) above the average of his race. . . . There are no postural defects and no skeletal disproportion or asymmetry. The spinal furrow is not completely flattened at any point, and when the arms are raised above the head there is no 'winging' of the scapulae. When he touches his toes, the vertebral column forms a smooth curve without definite flattening at any point. His skin has the 'bloom' of vigorous health, and is smooth, soft, elastic and slightly moist to the touch. There is a moderate amount of subcutaneous tissue over firm and well-developed muscles. He has no pot-belly, and no palpable spleen or liver. His eyes show a clear cornea surrounded by a white smooth sclerotic with little visible vascularisation, and during inspection there is no undue photophobia or watering. His vision, by night or by day, is excellent. The teeth are regular, and, in the absence of infective gingivitis, are set in firm and healthy gums. The tongue is neither too large nor too small, with no more than a slight fur, and there is no discolouration, fissuring, stripping of the epithelium or enlargement or flattening of the papillae. The mucous membranes are well-coloured and healthy. Blood examination would show normal haemoglobin content and red cells of normal appearance and size. The appetite is good and bowel function regular. The fit and well-nourished soldier gives an impression of alertness and vitality which is the opposite of apathy and listlessness. . . . When trained hard, he shows outstanding endurance, both physical and mental, and can go short of food, when necessary, without showing ill-effects for a considerable time. . . ."

"The malnourished soldier . . . At an early stage, the symptoms are generally non-specific—impairment of endurance, vitality and resistance to disease, slow recovery from disease or even impaired morale. The diagnosis is then one of considerable difficulty and can be made with assurance only after full investigation of the previous history and dietary, and full consideration of the differential diagnosis. At a later stage depletion of the nutritional reserves reaches a stage when more or less specific signs and symptoms appear. Again, the picture is not necessarily clear cut; if calorie intake has been so low as to cause inanition, specific deficiency lesions may be masked, or residual signs from malnutrition in the past may persist and confuse the issue. The presence of infectious disease may also modify the picture. The onset of malnutrition is generally very insidious; the lack of dramatic manifestations may lower standards of judgement so that an impaired level of health is taken as 'normal'. In the final stage, the picture becomes that of severe inanition or one of the classical deficiency

diseases. . . . All clinical impressions should be confirmed by finding out whether the diet has been such as to cause the type of malnutrition suspected, and all causes of secondary [conditioned] malnutrition should be looked for."

The belief that differences of nutritional status may be apparent to the discerning eye, even in the absence of objectively measurable criteria, is insistent and certainly correct. Thomson, Verma and Dilwali (1946) noted that in a feeding experiment among Indian Army recruits "A nutritious diet . . . caused a gain in weight amounting to about 5 to 10 per cent. of their initial weight within 3 to 4 months. There was also a marked clinical improvement, which, however, was not accurately reflected in a record of the incidence of certain specific signs attributed to chronic malnutrition", that is to say, signs which were then attributed to specific deficiencies. In the latter half of the war, the average Indian infantryman at enlistment was a smallish, thin individual with spindly limbs, a rough dry skin and often many signs of what appeared to be specific nutritional deficiencies, including mild hypochromic anaemia. "This picture became so uniform that it was something of a shock to come across a group of soldiers conforming to the highest standard that India can produce. On rare occasions one would meet a group of men about 6 feet tall, towering above other troops with them, and manifestly of excellent physique. It was difficult to believe that these were also Indians" (Thomson, 1946). The recovery of starved children during the Bengal famine of 1943 afforded another illustration. Refeeding with a diet based on milk not only restored these children but produced an appearance of liveliness and blooming health such as was seldom seen in the ordinary children of an Indian village (Thomson *et al.*, 1946). Such contrasts are dramatic, and were easily apprehended just because they existed together. How much more difficult is judgment in a more uniform population where the extremes differ by much less and are seldom seen together.

The technique of passing a general clinical judgment on nutritional status, after a clinical examination, has been widely used by the school medical service in Britain. The so-called "Dunfermline Scale" is used, in which children are placed in one of four groups ranging from "excellent" to "bad", and the findings are reported year by year in the reports of the Chief Medical Officer of the Board (now Ministry) of Education. In 1947 the description of these grades was changed from "nutritional state" to "general condition". Jones (1938) first cast doubt upon the worth of this method by showing that there was substantial disagreement between experienced physicians classifying and re-classify-

ing the same children and that a simple mathematical expression of body size, Tuxford's index (see below), was more successful in picking out "malnourished" children than the judgment of two or more experienced physicians. Almost simultaneously Derryberry (1938) drew similar conclusions from an analysis of the data of a survey made in 1929. Later Bransby and Hammond (1950) made a similar report.

Somatometric Measurements

Most of the earlier somatometric indices of nutritional status were expressions of height in relation to weight, sometimes involving powers of height or weight, which did not take age into account. Later, measurements of breadth and girth, *e.g.*, girth of chest and arm, width of pelvis, were added, or even used alone. Such measures are more likely to reflect the somatotype (body build) than the modifications of growth and form which may be produced by the environment. Tuxford (1917) devised an index derived from the height, weight and age relationships shown by London schoolchildren and yielding a mean value of 1.00 at all ages. Jones (1938) found Tuxford's index a more effective measure of poor nutrition than any individual clinical judgment. Tuxford (1942) revised his index to fit the measurements given by London schoolchildren in 1938. Campbell and Weir (1948) used the 1938 index to trace secular changes in growth among schoolchildren since 1905. They found that when it was applied to the English boys on whose measurements the original index had been based its value was 0.980 at age 3½ and fell steadily to 0.872 at 14½ years. For girls the corresponding values were 0.998 and 0.853. London schoolchildren in 1938 were not only taller at all ages but on the average also about 7.5 per cent. heavier for their increased heights than children in the period 1905-12, and "this indicates a substantial improvement in nutrition, greater at higher than at lower ages". Data for Glasgow schoolchildren between 1910 and 1945 were then compared. The index value rose during the period, but even in 1945 did not reach the 1938 London values. Campbell and Weir say "the fact that the index for the 13 year old children is now almost as high as at 5 years old, *i.e.*, that the previous deterioration with age has almost disappeared, taken in conjunction with the time sequence of the changes, suggests that the improvement is related to the provision of first milk, and then milk and meals, in schools". They say that with a continuously improving school population, the index may require frequent revision in order to effect correct grading, but "there can be no doubt that the index can be most useful now to follow secular

trends; to compare the status of different groups; to select the genuinely undernourished from groups of children and to assess the response to treatment".

It can be taken as proved that weight for height in relation to age is a useful tool for assessing the nutritional status of groups of children. This is confirmed by the Carnegie Survey data, which also demonstrate the response to improved feeding.

A currently popular device for using age/height/weight relationships is Wetzel's "grid" and its variants, in which growth along a given channel is considered to indicate satisfactory nutrition, while migration of the growth curve to lower channels indicates impairment. The origin of the norms used is not indicated. Wetzel (1941) claimed that the grid distinguished 94.5 per cent. of children judged to be in poor or borderline health by physicians and (1943) that the trends shown could reveal oncoming malnutrition 2 to 5 years before the clinical picture became sufficiently manifest to call for treatment. On the other hand, Leeson, McHenry and Mosley (1947) found that the opinion of an examining physician agreed with the "grid" evaluation in only half their cases, and thought that the somatometric data should be used in conjunction with an adequate physical examination. Wetzel's grid was, of course, designed to assess the nutritional status of the individual child and is probably no better and no worse than any other similarly based somatometric index. Like others, it will screen in accordance with the material from which it is derived; in addition, deviation downwards of a line may mean not deterioration but improvement of health, with a sudden spurt of linear growth with which weight gain has not kept pace (Lamberts, 1952).

Procedures for Surveys

In the search for uniformity of procedure in surveys, elaborate schedules for somatometric and clinical examination have been drawn up, e.g., by the U.S. National Research Council (1949), which says "Standardization of survey methods has worked well for the physical scientists and especially for the astronomers. . . . Therefore, in order to provide comparable data in the field of nutrition which can be read critically by any competent surveyor, a plea is made for standardization." While such sentiments and procedures are admirable in principle, they do not resolve the basic difficulties. Bean (1948) found significant differences between the observations of a group of physicians *trained in clinical nutrition and using a set of objective standards* when examining soldiers for signs of deficiency. "Data on the incidence of deficiency diseases, degree of severity and response to therapy acquire the aura of accuracy

when tabulated and dealt with mathematically. . . . No conclusions can be more valid than the data upon which they are based. Not only is the interpretation of sign and symptom a matter for dispute but the data just presented demonstrate that physicians trained in the clinical discipline of nutrition vary significantly in what they actually see in examining a person." This is certainly true of incipient deficiency states, where the clinical signs are "nondescript and variable".

If the biological astronomer has difficulty in maintaining a uniform standard of observation, his material also is troublesome. The stars remain in their courses, but human beings are constantly in a state of biochemical flux skilfully designed to give the appearance of stability. If one pathway of metabolism is blocked by lack of some enzyme or building-stone there are wide powers of adjustment to reach approximately the same end by alternative pathways.

Many ingenious methods have been evolved to obtain permanent records of physical characteristics, or in the hope of increasing the objectivity of clinical data. For example, Squires (1953a) described a method of making permanent records of tongue patterns. He (1953b) has also investigated the relationship of fluorescence of the tongue to nutritional status. Measurements of body fat, by skin folds or radiographic means, have received considerable attention in recent years. Regarded as research procedures in the evaluation of changes in body composition resulting from under- or over-feeding, such measurements have considerable interest (Brožek and Keys, 1950), but there are signs that skin fold measurements may be used uncritically and almost certainly without justification as a routine procedure in the general evaluation of "nutritional status".

The idea that functional impairment precedes the appearance of structural changes led to the study of tests of physical fitness, e.g., the Harvard step test, but the relevance of the results to nutritional status is doubtful. Indeed, the U.S. National Research Council (1949) goes so far as to say that it does not recommend the use of any "fitness tests" in general surveys.

X-ray photographs of the developing skeleton have been used to assess skeletal maturity in relation to nutritional status (Schmidt, 1941; Abbott *et al.*, 1950). Atlases of ossification pattern in well developed children have been prepared as standards against which to compare the skeletal maturity of children under investigation. These are, without doubt, an important contribution to knowledge of the physiology of growth and they would certainly help in the diagnosis of metabolic errors of bone growth, but there is no evidence to show that they add anything to the diagnosis of malnutrition that the

cruder study of body measurements will not provide.

The search for indices of nutritional status has led to the use of biochemical measures in bewildering profusion. Some of these have been discussed in the section dealing with specific criteria, where their generally unhelpful nature is apparent. While admitting the difficulties, the U.S. National Research Council (1949) thinks that, in future, biochemical examination will undoubtedly be an integral part of all nutrition surveys. And so the search continues. It has not failed to throw up non-specific criteria, *e.g.*, the level of cholinesterase in the blood plasma. The function of this enzyme appears to be unknown, but its activity in plasma has been found to fall in fairly severe underfeeding and to rise with increased food consumption (Hutchinson, McCance and Widdowson, 1951). Whether its estimation is of any value in detecting minor degrees of underfeeding is doubtful, and there is certainly no reason to think that it will be useful in the detection of incipient or mild malnutrition (Saunders *et al.*, 1952).

THE OUTLOOK

The first lesson to be drawn from the evidence discussed is that specific criteria of malnutrition short of frank deficiency disease have not been discovered. This does not mean that most of the groups studied have been adequately fed, *i.e.*, that they were not malnourished. As Thomson, Verma and Dilwali (1946) found, the use of specific clinical signs of malnutrition was of little value even in assessing the progress towards health of a group of undoubtedly malnourished Indian recruits, and the non-specific signs could not be reduced to objectively measurable entities. Again, malnutrition was undoubtedly common among children from the poorer strata of British society before the war, but carefully recorded lists of signs and symptoms failed miserably, for the most part, to distinguish between the ill fed and the well fed, and there was no change, except in growth, attributable to improved feeding over about a year (Carnegie Survey). Again, carefully controlled experiments in human malnutrition have failed to produce criteria whereby the prodromal stages can be recognised with any certainty.

It may well be that the concept of "biochemical lesions" leading to impairment of health short of deficiency disease has been thoroughly misleading. Many of the vitamins fulfil the roles of enzymes or take part in enzyme reactions, or are otherwise intimately concerned with energy conversion or metabolism of structural materials. Enough may be sufficient; there may be little or no "twilight zone", in terms of health, between, say, saturation and manifest deficiency. It is, of course,

possible that this may not be so in the growing child, and that the stages of deficiency before signs appear might be characterised by slowing of growth. But in ordinary life, deficiency of vitamins will almost never occur without simultaneous deficiency of structural material, particularly of calcium and protein, and it will be impossible to remedy deficiency of protein or calcium with any natural food without adding at least the B vitamins.

The most clear-cut biochemical data show that malnutrition can occur without obviously abnormal nutrient levels in blood or tissues, or that the nutrients fall to extremely low levels before clinical impairment is manifest. What we are looking for is not biochemical indications of impending catastrophe but the characterisation of a hypothetical twilight zone between optimum health and deficiency disease. What has been done so far is to demonstrate a relationship between diet and some biochemical levels, but these furnish, at present, little more than a partial and unsatisfactory alternative to diet surveys.

Other nutrients, *e.g.*, calcium, fulfil a structural role. Here there may be a much wider zone between abundance and structural failure. Scarcity of supply is met with economy of utilisation and the main manifestations of malnutrition will be in relation to growth and form, not to function and detailed structure. In children, even when they have been fully safeguarded against rickets and other possible deficiency disease, malnutrition may still result from slight underfeeding with relative shortage of some structural material. On this basis, it is reasonable to expect that growth will be restricted to the rate permitted by the material in shortest supply, most probably calcium or protein.

The second lesson to be drawn from the evidence is that since the organism must be healthy to grow satisfactorily, growth is a good measure of general health, and since growth is the product of nutrition it measures nutritional status. It is true that acute infections slow or arrest growth, but in the well fed child such delays are rapidly and fully overtaken. Vital statistics and studies of the social distribution of growth rates and attained statures all show that superior growth rates and heights correlate well with superior health. For example, the publications of Baird and his team (Baird, 1945; 1949; 1952b) show that tall women experience lower rates of stillbirth, prematurity (birthweight 5.5 lb. or less) and dystocia; while human growth studies such as those of Campbell and Weir (1948) show that improving nutritional conditions among schoolchildren are paralleled by improved rates of growth.

The assessment of growth in relation to nutrition is complicated by innate differences of body type and growth potential, but many of these difficulties

can be avoided by using the fact that the evolution of adult body shape involves an orderly sequence of changes in body proportions (Leitch, 1951; Hammond, 1953). The ratio of cristal height to total height changes from about 0.33 at birth to 0.66, the maximum so far recorded in well built adults. In brief, the pattern of normal growth from foetal life into adulthood implies relatively greater growth in leg than in trunk length. Under conditions of poor nutrition with slowed rate of growth, the ratio of leg length to total height remains relatively immature, i.e., numerically low. This suggests that individual children or groups of children of a given age with relatively short legs will be poorly nourished and in poor states of health. The hypothesis was tested directly on the data of the Carnegie U.K. Dietary and Clinical Survey, and has been found to hold good. The ratio of leg length (cristal height) to total height was found to differentiate more sensitively than total height between children in different food expenditure and age groups. The suggestion is therefore made that leg length in relation to total height and age will be one of the most satisfactory indices of nutritional status in children. If it is true that ill-grown children become adults with some of the somatometric characteristics of immaturity, it will be useful also among adults.

The index has the merit of being relatively insensitive to short-term changes in nutrition, which may cause rapid changes in bodyweight and hence affect indices based on height, bodyweight and age. Such indices may, of course, be of special value when the intention is to assess suspected changes of nutritional status within a population, e.g., in war time. Considerable care in their interpretation is necessary since, while it is probably impossible to become too tall as a result of overfeeding, it is certainly possible to become too fat. Adult bodyweight is particularly suspect in this connection, overweight being definitely correlated with high mortality (Breslow, 1952), so that a falling bodyweight among the adult population may imply improving health and not, as suggested by Harries and Hollingsworth (1953), the reverse.

To sum up, future studies of growth in relation to nutrition should be more clearly related to primary patterns of development than are some of the esoteric somatometric indices devised in the past to fit arbitrarily selected data. The use of an inherent pattern provides an internal standard.

Arising from this there is a most important question. Does the slowing of growth and its arrest while the form of the body is still relatively immature mean parallel impairment of the *elan vital*? Does it imply that the stunted adult lacks vitality?

How does one define and measure vitality? This is a matter of no small difficulty in respect of

individuals, but for populations the use of vital statistics merits consideration. If there is any exception to the rule that well fed populations have a favourable mortality experience, and vice versa, we are not aware of it. The correlation is, however, a crude one which can be interpreted in terms of nutritional causation only with great difficulty. The use of antibiotics to control infectious diseases by elimination of organisms in the environment and in the body, as is at present happening in the Middle and Far East, means that abrupt changes in mortality experience can occur without any concurrent change in host resistance. People so freed from the burden of infectious disease will as a consequence improve food production and their standard of living, so that the deficiency diseases will be reduced or disappear; their vital statistics will only then approach those of Western Europe and North America. In a community with little infection and a high standard of living, mortality rates in general are low although a host of "degenerative diseases", affecting mainly the middle and later years of life, keep the doctors busy. They are, probably, due in part to overfeeding, and control of energy intake would almost certainly produce a further fall of mortality. There is some evidence of this in the reduction of death rates from hypertensive and cardiovascular diseases that occurred in Western Europe during the war years. For a review see Strøm and Rygh (1952).

Ideally, the best mortality statistic to use as an index of malnutrition would be one which depended little on either infectious or senile degenerative processes, but which was influenced by the physiological efficiency of the organism at its prime. No ideal mortality rate exists, but the neonatal death rate or, even better, the first-week death rate is probably one of the best, because a substantial proportion of deaths in the earliest period of life are due to prematurity with no obvious pathological cause (Joint Committee of Royal College of Obstetricians and Gynaecologists and British Paediatric Association, 1949; Baird, 1953). Duncan, Baird and Thomson (1952) and Baird, Thomson and Duncan (1953) have discussed the behaviour of the first-week death rate and of the stillbirth rate, and suggest that trends in this country during the war years are difficult to explain except on the hypothesis of improved maternal nutrition.

It is unfortunate that clinical observation has so seldom been linked to measurements of diet. Both, undertaken together, are essential if the relations of health to diet are to be understood. Logic has sometimes been forgotten in differentiating between dietary standards set up as minima for health and those set up as optima. It is too easily assumed that because standards for any

nutrient can be placed on one quantitative continuum there is a similar continuum in respect of health: "the more food, the better for health". This is certainly not universally true. Because it is so difficult to define and measure the consequences for health of sub-optimum but not disease-producing diets, nutrient standards in common use are derived not from any intimate relation of the several nutrients to health, but from records of the ordinary diets eaten by healthy people. As social targets they are obviously valid and desirable, but, if a given population fails to reach the appropriate target, this is not to say that it must be suffering from any clinically demonstrable defect of health, though in the long run defects of growth, or poor morbidity and mortality statistics, might differentiate it.

It might be thought that the failure of "minor"

signs, symptoms and biochemical phenomena to provide us with practical measures of malnutrition in a relatively well-nourished community, such as that of present-day Britain, leaves us barren of resources. This is not so. Within the past 15 years there has been a remarkable acceleration in the growth of children, accompanied by imponderable but obvious improvements in health and by reductions of mortality, which no one in 1938 could have predicted. To attribute these, at least in part, to the concurrent improvement of national nutrition is not unreasonable. Many defects remain and even deficiency disease is not yet unknown. We have the salutary warning of Brailsford (1953) that the subperiosteal haemorrhage of scurvy in infants has recently been mistaken for sarcoma.

roval'noi bumage. [Modification of the method of electrophoretic separation of proteins on filter paper.] *Biokhimiya*, 1953, **18**, 34-36. [Inst. Biol. Khim., Akad. Med. Nauk. SSSR, Moscow.]

A simple apparatus is described with which blood serum proteins were separated satisfactorily by electrophoresis. It consists of a glass tank $40 \times 60 \times 20$ cm. covered with a glass plate. The filter papers which are fed with buffer solution and on which the proteins are separated are freely suspended in the tank on glass rods fixed to the sides of the tank, the free ends of the filter papers being immersed in the electrode vessels. The air in the tank is saturated with water vapour from a layer of water on the floor of the tank; the electrode vessels are three 700- to 800-ml. beakers. Two filter papers can be used simultaneously. The middle beaker contains the cathode and the two others contain anodes. The electrodes themselves are specially constructed so that the needle electrodes employed are not in direct contact with the buffer solution contained in the beakers and the pH changes which occur near the needle electrodes are not easily transmitted to the papers. For the separation of blood serum proteins, veronal of pH 8.6 and ionic strength 0.1 was the buffer. After electrophoresis for 20 to 24 hr. the papers were dried and treated with 1 per cent. bromophenol blue in 59 per cent. ethanol saturated with $HgCl_2$.—W. Hughes.

7

CUENDET, L. S., MONTGOMERY, R. and SMITH, F. Cellulose sheets as chromatographic supports. *J. Amer. Chem. Soc.*, 1953, **75**, 2764-2765. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

Cellulose sheets, $\frac{1}{8}$ in. thick, have high loading capacities but owing to their poor wet strength can be used only in horizontal development chromatography. An apparatus is described.

H. G. Bray.

ANALYTICAL METHODS

General

8

SCHLÖGL, K. and SIEGEL, A. Eine einfache Methode zur weiteren Auftrennung papierchromatographisch vorgetrennter Substanzgemische. [A simple method for the further separation of mixtures of substances previously

separated by paper chromatography.] *Hoppe-Seyler's Ztschr.*, 1953, **292**, 263-268. [2. Chem. Lab., Univ. Vienna.]

In the method described for the further separation of substances already separated by paper chromatography, the "spots" requiring further investigation are cut out from the first chromatogram, and fixed between glass strips at the start of another chromatogram. If desired, changes of paper or solutions may be made in the new chromatogram to give more exact identification. Several examples are described illustrating the possibilities of the method.—M. B. Richards.

9

ZAHN, R. K. and STAHL, I. Die kontinuierliche Extraktion von Stoffgemischen unter Änderung eines Parameters nach dem Volum-Ersatzprinzip. [Continuous extraction of mixtures of substances with alteration of a parameter according to the volume replacement principle.] *Hoppe-Seyler's Ztschr.*, 1953, **293**, 1-10. [Inst. Chem. Physiol., Johann-Wolfgang-Goethe-Univ., Frankfurt a.M.]

In this method of continuous extraction a precipitate of the protein mixture to be separated is thrown down on a suitable carrier substance in a column through which filters a solution of ammonium sulphate. By means of the apparatus illustrated the solution undergoes continuous dilution on the volume replacement principle, so that the components of the precipitate are successively extracted according to their solubility, and are collected in different fractions. The method can be varied for the extraction of other substances, and the mathematical treatment of the parameter changes is described.—M. B. Richards.

Carbohydrate Constituents

10

GAILLARD, B. D. E. Use of unneutralized hydrolysates in paper chromatography of sugars. *Nature*, 1953, **171**, 1160. [Lab. Animal Physiol., Agric. Univ. Coll., Wageningen.]

If an acid spray such as aniline phosphate or phthalate is used, polysaccharide hydrolysates prepared with H_2SO_4 need not be neutralised before qualitative or quantitative chromatography.

H. G. Bray.

11

GIRI, K. V. and NIGAM, V. N. Separation of simple saccharides and oligosaccharides by circular paper chromatography. *Naturwissenschaften*, 1953, **40**, 343-344. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

The circular filter paper technique previously described for separating amino-acids can be used for the separation of saccharides and oligosaccharides, with *n*-butanol-acetone-water (20 : 70 : 10) as

solvent mixture and aniline-diphenylamine phosphate as detecting reagent.—H. G. Bray.

12

TAKATA, M., TAKAHASHI, Y. and SASAKI, K. Eine neue Mikromethode zur Bestimmung des Blutzuckers (Perjodat - Methode). [A new micromethod for estimating blood sugar (periodate method).] *Klin. Wochenschr.*, 1953, **31**, 590-593. [Med. Chem. Inst., Toho Univ., Tokyo.]

13

PROKHOVNIK, S. J. and NELSON, J. F. Determination of blood sugar with anthrone. *Austral. J. Exp. Biol. Med. Sci.*, 1953, **31**, 279-282. [Dept. Physiol., Univ. Melbourne.]

The method is applicable to amounts of glucose of from 6 to 100 μg . and is most precise for 40 to 60 μg . A zinc hydroxide blood filtrate is prepared and treated with a solution of anthrone in concentrated H_2SO_4 and heated in a boiling-water bath and the colour produced is estimated.

H. G. Bray.

14

LUNT, E. and SUTCLIFFE, D. A new calorimetric reagent for carbohydrates. *Biochem. J.*, 1953, **55**, 122-126. [Dept. Exp. Pathol., Univ. Birmingham.]

The reagent is resorcinol-4 : 6-disulphonic acid ; its use is similar to that of anthrone, but it has the advantage of being more stable. The method is applicable to 10 to 250 μg . glucose in 5 ml. solution and is accurate to within 1 per cent.—H. G. Bray.

15

BERTRAND, D. Remarques à propos du microdosage des sucres réducteurs. [Remarks on the micro-estimation of reducing sugars.] *Bull. Soc. Chim. biol.*, 1953, **35**, 865-867.

It is shown that the original Bertrand method (*Bull. Soc. Chem.*, 1906, [iii], **35**, 1285) can be adapted for the micro-estimation of sugars provided the use of a large excess of alkaline copper solution is avoided and the excess Cu remaining after reduction is estimated with a photo-electric colorimeter. As little as 0.25 to 1.5 mg. of glucose can be estimated with an error not exceeding 0.025 mg.—W. Godden.

16

BOREL, E. and DEUEL, H. Quantitative Zuckerbestimmung mit 3, 4-Dinitrobenzoesäure. [Quantitative estimation of sugars with 3 : 4-dinitrobenzoic acid.] *Helv. chim. Acta*, 1953, **36**, 801-807. [Inst. Agric. Chem., Tech. Hochsch., Zürich.]

The reduction product, under alkaline conditions, of 3 : 4-dinitrobenzoic acid and sugars was

N.A. and R., January 1954

shown to be 3-nitro-4-hydroxylaminobenzoic acid. A procedure is described for the estimation of from 0.05 to 0.5 mg. of sugars, the absorption being measured at 548 m μ . The method is applicable to components of polysaccharide hydrolysates separated by paper chromatography.

H. G. Bray.

17

JONES, J. K. N. and PRIDHAM, J. B. **A colorimetric estimation of sugars using benzidine.** *Nature*, 1953, **172**, 161. [Dept. Biol. Chem., Univ. Bristol.]

The sugar solution is treated in a boiling-water bath with a 0.2 per cent. solution of benzidine in glacial acetic acid and the orange-yellow colour is estimated photometrically. The method is applicable to 0.1 mg. per ml. concentrations of most common sugars and their methylated derivatives, but not to ketoses, with an accuracy within 3 per cent.—H. G. Bray.

18

FONG, J., SCHAFER, F. L. and KIRK, P. L. **The ultramicrodetermination of glycogen in liver. A comparison of the anthrone and reducing-sugar methods.** *Arch. Biochem. Biophys.*, 1953, **45**, 319–326. [Div. Biochem., Univ. California, Berkeley.]

HADORN, H. and BIEFER, K. W. **Über polarimetrische und titrimetrische Stärkebestimmungen in Lebensmitteln. [Polarimetric and titrimetric estimation of starch in foods.]** *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 276–292. [Lab. VSK, Basle.] French and English summaries.

Methods of estimating starch are reviewed. The method recommended for general use is a modification of that of Baumann and Grossfeld (*Ztschr. Untersuch. Lebensmittel*, 1917, **33**, 97). The method of Mannich and Lenz (*Ztschr. Untersuch. Lebensmittel*, 1920, **40**, 1) is suitable for flour, but not for materials containing soluble starch.

H. G. Bray.

23

SCHARPENSEEL, H. W. **Vergleichende Untersuchungen zur Rohfaserbestimmung und Ermittlung des Produktionswertes von Rauh-futtermitteln. [Comparative study of methods of estimating crude fibre and assessing the production value of roughages.]** *Arch. Tierernährung*, 1952, **3**, 137–144. [Inst. Tierzucht, Univ. Bonn.]

Crude fibre was estimated in 21 different types of feedingstuffs by Lepper's modification of the Weende method (Abst. 3833, Vol. 3), by the method of Puranen and Tomula (*Ztschr. Untersuch. Lebensmittel*, 1936, **72**, 111) and by that of Leitenberger and Opl (*Die Bodenkultur*, 1944, **3**, part 4). The third method gave good agreement with the first taken as standard and, on account of the small amount of manipulation required, is well suited to long series of analyses. The second method often gave results differing widely from those of the other two.

It is argued that, for coarse fodders, the correction of starch value by deduction of 0.58 times the percentage of crude fibre is not adequate and that a deduction should be made for lignin content. The author finds by calculation that this deduction may be from 0.95 to 2.55 units of starch value for each 1 per cent. of lignin, but urges that respiration experiments should be undertaken to ascertain the true factor.—W. Godden.

Nitrogenous Constituents

24

PERRIN, C. H. **Rapid modified procedure for determination of Kjeldahl nitrogen.** *Anal. Chem.*, 1953, **25**, 968–971. [Canada Packers, Ltd., Toronto.]

A study was made of the efficiency of digestion mixtures towards nicotinic acid and a new formula was devised, containing HgO, K₂SO₄ and H₂SO₄. The digestion time is 13 to 20 min. and the endpoint can be detected visually.—H. G. Bray.

KIMBEL, K. H. and AMON, M. Über die Brauchbarkeit der Invertseifentitration zur Proteinbestimmung in biologischem Material. [On the possibility of using the invert soap titration to estimate protein in biological material.] *Hoppe-Seyler's Ztschr.*, 1953, **293**, 98-105. [Med. Klin., Univ. Würzburg.]
Seven ammonium bases, of which 6 were commercial disinfectants, were tested for their suitability for estimating the protein content of biological fluids. It was found that the invert soap titration with all the preparations tested gave reproducible results in pure protein solutions in the concentration range 0.02 to 0.2 per cent. This was shown for solutions of human albumin and γ -globulin. In each case there was linear dependence of the titration end-point on the protein concentration, but considerable differences were found in the values obtained for albumin and γ -globulin solutions of like concentration. The presence of certain urinary constituents in molar or 0.1 *M* concentration caused marked deviations in the results with all the preparations. In presence of Mg, precipitation of colloidal $Mg(OH)_2$ made titration impossible except in concentrations

below 0.01 *M*. The titration values of a 0.1 per cent. albumin solution showed a marked dependence on the hydrogen ion concentration between *pH* 7 and *pH* 13. The method cannot be recommended for the analysis of urine or serum.

M. B. Richards.

35

KARUNINA, L. and SHILOVICH, M. Proverka metodov bystrogo opredeleniya kolichestva belka v moloche. [Examination of methods for rapid estimation of protein in milk.] *Mol. Prom.*, 1953, 14, No. 2, 25-28. [Vse-Soyuz. Nauch-Issled. Inst. Mol. Prom.]

Comparison of the formaldehyde and amide N methods for estimating protein in milk, with the Kjeldahl method as control, indicated that the amide N method gives more accurate results but takes longer than the formaldehyde method. The protein content of bulked milk and milk from individual cows varied by the formaldehyde method between ± 5 per cent. of the Kjeldahl values, but with the amide N method 81 per cent. of the values differed from the Kjeldahl values by less than ± 3 per cent.—W. Hughes.

36

PERNIS, B. and WUNDERLY, C. Quantitative determination of amino acids on filter paper. Staining in two stages. *Biochim. biophys. Acta*, 1953, 11, 209-214. [Med. Clin., Univ. Cagliari, Italy.] French and German summaries.

The developed chromatogram is sprayed with a buffered ninhydrin reagent and the colour is developed. The spots are outlined, cut out and treated with a further amount of the reagent. After heating and cooling, propanol is added and the colour is measured photometrically. The necessary controls are described in detail.

Investigation of Naftalin's method for the estimation of amino-acids on paper chromatograms (Abst. 1598, Vol. 18) showed that the nature of the acid used for protein hydrolysis and the use of de-salting techniques had considerable effects on the results.—C. Warner.

38

PRIOR, A. P. and WHITEHEAD, T. P. Paper chromatography of amino-acids in cerebrospinal fluid. *Nature*, 1953, 172, 358-359.

Vol. 24, No. 1

[S. Warwickshire Hosp. Group (No. 14), Group Pathol. Lab., Lakin Rd., Warwick.]

From the chromatographic estimation of amino-acids in cerebrospinal fluid, the fluid is freed from proteins and anions by passing it through a suitable cation exchange resin (Zeo-Karb 225). The amino-acids are retained on the column, from which they are displaced with ammonia. The resulting eluate is evaporated under reduced pressure and the dry residue, taken up with water, is used for paper chromatography. Cerebrospinal fluid of high protein content can be passed through the column without the *pH* changes in the column altering the free amino-acid pattern of the fluid. By combining this technique with the circular filter-paper method of paper chromatography, results can be obtained within 4 hr. of receiving the fluid. Preliminary results show that the method is suitable for serum and urine.

M. B. Richards.

39

CURZON, G. and GILTROW, J. A chromatographic colour reagent for a group of amino-acids. *Nature*, 1953, 172, 356-357. [Dept. Biochem., Inst. Orthopaedics, Brockley Hill, Stanmore, Middlesex.]

Vanillin followed by ethanolic potash has proved to be a chromatographic reagent of considerable specificity. The minimum detectable quantities of the substances giving well-defined colours in daylight, when run on 15 cm. one-way acetone-urea-water chromatograms, are, in $\mu\text{g.}$: ornithine 0.5, sarcosine 0.5, proline 1, hydroxyproline 1, α -pipecolic acid 1, baikiain 1, β -pipecolic acid 4 and γ -pipecolic acid 5. Ornithine gives a salmon spot about 30 sec. after heating commences. The other substances show up as red spots after about 6 hr. and reach maximum intensity in 16 hr.; β - and γ -pipecolic acids give comparatively faint colours. A large number of amino-acids tested gave indefinite or negative results.—M. B. Richards.

40

CHRISTOMANOS, A. A. Zur electrophotometrischen Papierchromatographie der Aminosäuren. [Electrophotometric paper chromatography of amino-acids.] *Enzymologia*, 1953, 16, 87-90. [2 Biochem. Abt., Univ. Athens.]

The intensity of the ninhydrin colour given by the bands is estimated by direct spectrophotometry. The method is applicable to autolysates, hydrolysates and clinical material.—H. G. Bray.

41

RAO, T. and GIRI, K. V. Circular paper chromatography. 5. The separation, identification and quantitative determination of urea with application to human urine.

GIRI, K. V., RADHAKRISHNAN, A. N. and VAIDYANATHAN, C. S. **6. The quantitative determination of amino acids.** *J. Indian Inst. Sci.* [A], 1953, **35**, 137-143; 145-180. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

5. The developing solvent is a mixture of *n*-butanol, acetic acid and water (40:10:50). Half the developed chromatogram is sprayed with a phenol-hypochlorite reagent, the corresponding bands on the unsprayed half are cut out and eluted and the urea is estimated colorimetrically with α -isonitrosopropiophenone.

6. Previously described methods are reviewed and a method depending on circular paper chromatography is described in detail. The amino-acids separated with the mixture of *n*-butanol, acetic acid and water (40:10:50) are detected with ninhydrin and eluted with 75 per cent. ethanol containing copper sulphate, and the colour is compared with that given by a standard run simultaneously.—H. G. Bray.

42

WILTSHIRE, G. H. **The estimation of D- and L-glutamic acid in proteins.** *Biochem. J.*, 1953, **55**, 46-49. [Biochem. Lab., Univ. Cambridge.]

D-Glutamic acid was computed by difference, total glutamic acid being estimated by an ion exchange procedure with Amberlite IR-4B, and L-glutamic acid by enzymic decarboxylation. Five per cent. of L-glutamic acid is converted to the D-isomer during the preliminary treatment of proteins, but more than this was found in hydrolysates of alkali-treated protein and also in the cells of *Lactobacillus casei*, though not in several plant, animal and virus proteins studied.

KOCH, R. and HANSON, H. **Zur Papierchromatographie von Glutamin- und Asparaginsäure. [Paper chromatography of glutamic and aspartic acids.]** *Hoppe-Seyler's Ztschr.*, 1953, **292**, 180-183. [Physiol. Chem. Inst., Martin-Luther-Univ., Halle a.d. Saale.]

It was shown by paper chromatography that glutamic and aspartic acids are esterified when kept in a solution containing ethanol and HCl. Neutral amino-acids are not affected.—H. G. Bray.

44

SCHRAM, E., DUSTIN, J. P., MOORE, S. and BIGWOOD, E. J. **Application de la chromatographie sur échangeur d'ions à l'étude de la composition des aliments en acides aminés. [Application of ion exchange chromatography to the study of the amino-acid content of foods.]** *Anal. chim. Acta*, 1953, **9**, 149-162.

[Lab. Biochim., Fac. Méd., Univ. Brussels.] English and German summaries.

The method used was that of Moore and Stein (Abst. 4469, Vol. 21) and is suitable for all common amino-acids except methionine, which is partly oxidised during acid hydrolysis, and tryptophan, for which no suitable method was found. Reference is made to a chromatographic method for the estimation of cysteine (as cysteic acid) in the presence of carbohydrate. Details are given of the application of the methods described to food materials.—H. G. Bray.

45

BAKER, C. G. and SOBER, H. A. **Application of ion exchange chromatography to enzymatic resolution of amino acids.** *J. Amer. Chem. Soc.*, 1953, **75**, 4058-4060. [Biochem. Lab., Nat. Cancer Inst., Bethesda, Md.]

The resins used are Dowex-50 and Amberlite XE-64. Asymmetric enzymic hydrolysis is applied to the N-acyl or amide derivatives of the amino-acids and the products are separated by elution from the column with water and with HCl. The procedure is applicable to amounts of the order of 0.3 to 1.0 g. The yields obtained ranged from 35 to 92 per cent.—H. G. Bray.

46

WALDSCHMIDT-LEITZ, E. and GAUSS, K. **Zur Bestimmung der carboxyl-endständigen Bausteine in Proteinen. [Estimation of protein constituents with end carboxyl groups.]** *Hoppe-Seyler's Ztschr.*, 1953, **293**, 10-16. [Inst. Org. Chem., Tech. Hochsch., Munich.]

Protein constituents with end carboxyl groups can be split off by carboxypeptidase, and identified by paper chromatography, taking into account the varying rates of enzymic separation of the different amino-acids, and their varying sensitivities towards ninhydrin. The method was applied to insulin and 3 different preparations of clupein. A suggestion is made for the nomenclature of proteins such that the constituents might be indicated by indices affixed to the name of the protein.—M. B. Richards.

47

JACOX, R. F. **Quantitative fractionation of component proteins of human serum with cationic detergents.** *J. Clin. Invest.*, 1953, **32**, 661-673. [Dept. Med., Sch. Med. Dent., Univ. Rochester, N.Y.]

The use of a cation detergent, octadecyldimethylbenzylammonium chloride ("Octab"), for the estimation of α -globulins, β - and γ -fractions, albumin and total protein is described. The procedure consists of treating diluted serum, 0.05 to

N.A. and R., January 1954

0.12 ml. diluted a hundredfold, under specified conditions of pH and salt concentration and measuring the optical density of the mixtures obtained.—H. G. Bray.

48

BODE, F. Die quantitative Bestimmung des Aminostickstoffs. [Quantitative estimation of amino-nitrogen.] *Experientia*, 1953, 9, 271-272. [Frankfurt a.M.] English summary.

A colorimetric method is described, based on the reaction of the α -amino-groups with ninhydrin and copper nitrate to give a red colour which can be measured spectrophotometrically at 510 m μ . A developed chromatogram is sprayed with a ninhydrin reagent and, after heating, with an acid-ethanolic copper nitrate solution. After drying, the coloured compound is eluted from the appropriate portions of the chromatogram by methanol and the colour intensity is measured.

A procedure is described for the estimation of peptides in urine.—H. G. Bray.

49

MEYER, H. and RIKLIS, E. Influence of cations on the ninhydrin reaction for the determination of amino-acids. *Nature*, 1953, 172, 543. [Dept. Biol. Chem., Hebrew Univ., Jerusalem.]

Traces of certain cations affect the speed of ninhydrin colour development and the nature of the absorption spectra of the products. This effect can be eliminated by adding "Versene" (disodium salt of ethylene tetra-acetic acid) to the reaction mixture. A procedure is described.

H. G. Bray.

50

FRASER, D. and HIGGINS, H. G. Spectrophotometric determination of amino-groups. *Nature*, 1953, 172, 459-460. [Div. Forest Products, C.S.I.R.O., Melbourne.]

A spectrophotometric investigation was made of the reaction between diazotised sulphanilic acid and glycine, lysine, arginine and tryptophan. The use of this reaction in estimating the amino-groups of amino-acids and proteins is discussed.

H. G. Bray.

51

ZALTA, J. P. and KHOUVINE, Y. Dosage de la lysine, de la tyrosine et de l'arginine. [Estimation of lysine, tyrosine and arginine.] *Bull. Soc. Chim. biol.*, 1953, 35, 697-701. [Inst. Biol. Phys. Chim., Paris.]

The method for lysine depends on the fact that on treatment with chloramine T it yields a product which gives a blue colour with the Folin Ciocalteu reagent. Lysine, 7 to 30 μ g., can be estimated within 5 per cent. Histidine interferes, but a correction can be made.

Vol. 24, No. 1

Tyrosine gives a cherry-red colour when treated with α -nitrosonaphthol. By the method described, based on this reaction, 5 to 30 μ g. tyrosine can be estimated within 3 per cent.

A modified Sakaguchi reaction is described for the estimation of arginine, applicable to amounts of 5 to 20 μ g. Urethane is used for the removal of excess hypobromite.—H. G. Bray.

52

UDENFRIEND, S. and COOPER, J. R. Assay of L-phenylalanine as phenylethylamine after enzymatic decarboxylation; application to isotopic studies. *J. Biol. Chem.*, 1953, 203, 953-960. [Lab. Chem. Pharmacol., Nat. Heart Inst., U.S. Pub. Health Serv., Bethesda, Md.]

The phenylalanine in tissues or protein hydrolysates is converted to phenylethylamine by incubation with an acetone powder preparation of *Streptococcus faecalis* obtained by Epps's method (*Biochem. J.*, 1945, 39, 42). It is extracted into chloroform containing 3.3 per cent. isoamyl alcohol and is estimated by a modification of the methyl orange procedure of Brodie and Udenfriend (*J. Biol. Chem.*, 1945, 158, 705). Details are given for the isolation of phenylethylamine hydrochloride from a hydrolysate of plasma proteins. It is obtained in sufficient quantity and purity for radio-active measurements after administration of 3-¹⁴C-DL-phenylalanine to animals or patients.

W. Godden.

53

KAWAMATA, J., TAKAHASHI, T. and YACHIKU, M. A microcolorimetric method for the determination of tryptophan with Tsuda's reagent. *Med. J. Osaka Univ. (Jap. Ed.)*, 1953, 5, 393-396. [Dept. Chemotherap., Inst. Microbial Dis., Univ. Osaka.] In Japanese: English summary.

The sample, 1 ml., containing tryptophan 0.005 to 0.25 mg., is treated with 1 ml. of 2*N* HCl and 1 ml. of 1 per cent. NaNO₂ at 30° C. for 30 min., the excess nitrous acid is decomposed with 4 ml. of 4 per cent. sulphamate, and 3 ml. of 0.2 per cent. 1-(β -diethylaminoethylamino)-naphthalene oxalate is added. The purple-red colour produced is estimated photometrically after 15 to 30 min. Kynurenine, anthranilic acid and abrine interfere, but not other amino-acids.—H. G. Bray.

54

FIGUEROA, E. S. and SEIBERT, F. B. Chromatography of α - ϵ -diaminopimelic acid on starch columns. *Proc. Soc. Exp. Biol. Med.*, 1953, 83, 535-537. [Henry Phipps Inst., Univ. Pennsylvania, Philadelphia.]

The amino-acid α - ϵ -diaminopimelic acid behaved like lysine when applied to starch columns; the

solvents used for application and elution were mixtures of *n*-butanol and *n*-propanol and 0.1 *N* HCl or *n*-propanol and 0.5 *N* HCl. Paper electrophoretic studies showed that the amino-acid migrated between glutamic acid and lysine in barbiturate buffer at *pH* 8.6.—G. A. Garton.

55

DAVIES, D. F., WOLFE, K. M. and PERRY, H. M. **Studies on primary amines. 1. Methods.** *J. Lab. Clin. Med.*, 1953, **41**, 802-811. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

Primary amines separated from biological fluids can be estimated by paper chromatography, with a pyridine-ninhydrin detecting reagent. This may be used also for the spectrophotometric estimation of the amines.—W. G. Bray.

56

STELGENS, P. Über die Kreatinkörperbestimmung mit Kaliumquecksilberrhodanid und Dithizon. 2. [Estimation of creatine bodies with potassium mercury thiocyanate and dithizone. 2.] *Biochem. Ztschr.*, 1953, **324**, 228-236. [Kinderklin., Univ. Heidelberg.]

With the potassium mercury thiocyanate and dithizone method, previously described for pure solutions (Abst. 3872, Vol. 23), creatinine and creatine were estimated in amounts of blood which could easily be taken from the finger tip. For 10 healthy adults the average values obtained were 0.75 mg. per cent. creatinine and 2.13 mg. per cent. creatine. Creatine bodies were also estimated in normal urine, and in the urine of patients with progressive muscular dystrophy and of dystrophic infants. Comparison of the results with those obtained by the picrate method showed the greater specificity of the new procedure. Satisfactory recoveries of added creatinine and creatine were obtained with both blood and urine. Heating urines on a boiling-water bath may lead to loss of creatinine. Treatment for 24 hr. at 60° to 65° C. is more suitable.—M. B. Richards.

57

ENNOR, A. H. and STOCKEN, L. A. **The application of the diacetyl reaction to the estimation of creatine in urine.** *Biochem. J.*, 1953, **55**, 310-314. [Dept. Biochem., John Curtin Sch. Med. Res., Australian Nat. Univ., Canberra.]

The method depends on the measurement of the rate of colour development with α -naphthol and diacetyl, in samples of urine before and after enzymic removal of creatine and in similar samples containing added known amounts of creatine and creatinine. The calculation of the result is graphical.—H. G. Bray.

58

ROSCOE, M. H. **The estimation of creatinine in serum.** *J. Clin. Pathol.*, 1953, **6**, 201-207. [Dept. Med., Univ. Manchester.]

A detailed study of the Jaffé reaction. A standard method is described.—H. G. Bray.

59

WALL, J. S. **Simultaneous separation of purines, pyrimidines, amino acids and other nitrogenous compounds by ion exchange chromatography.** *Anal. Chem.*, 1953, **25**, 950-953. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

A single column of Dowex-50 is used. The compounds under investigation are eluted with HCl and estimated by their ultraviolet spectra or by the ninhydrin reaction. It was found that 95 per cent. of the N of bacterial hydrolysates could be accounted for as 25 compounds.—H. G. Bray.

60

Lipoid Constituents

61

FILLERUP, D. L. and MEAD, J. F. **Chromatographic separation of the plasma lipids.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 574-577. [Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

Artificial mixtures of sterol esters, triglycerides, cholesterol, fatty acids and lecithin were effectively separated into their components by chromatography on silicic acid columns with increasingly polar eluents. The lipids were separated in the order given above by elution successively with 1, 4, 10 and 50 per cent. ether in light petroleum (b.p. 60° to 70° C.) and 25 per cent. methanol in ether. Human plasma lipids were similarly fractionated into sterol esters, triglycerides, sterols and phospholipids.

In a further experiment, 2 human subjects were each given 5 g. methyl β -elaeostearate by mouth; 4 hr. later blood was withdrawn from the antecubital vein and the plasma lipids were fractionated. β -Elaeostearic acid was found exclusively in the triglyceride fraction.—G. A. Garton.

62

HACK, M. H. **Analysis of lipids by spot tests on filter-paper disk chromatograms.** *Biochem. J.*, 1953, **54**, 602-605. [Dept. Anat., Univ. Chicago, Ill.]

A preliminary fractionation of lipids can be made by choosing a suitable solvent for the extraction of freeze-dried material. Chloroform-methanol mixture extracts total lipid, benzene extracts that not bound to protein and acetone extracts neutral fat, cholesterol and other non-phosphatide lipids. A spot of the lipid to be studied is applied to the centre of a filter paper disc and the chromatogram is developed by irrigation at the centre with solvent. Spot tests are described for the detection of choline lipids, amine lipids, acetal lipids (plasmalogens), phosphate esters, cholesterol and glycolipids. Plasmalogens were detected in some isolated lipids and in certain tissues.—H. G. Bray.

63

NÚÑEZ, G. and SPITERI, J. Chromatographie de partage des substances liposolubles. 1. Séparation des acides gras supérieurs. [Partition chromatography of fat-soluble substances. 1. Separation of higher fatty acids.] *Bull. Soc. Chim. biol.*, 1953, **35**, 851–857.

Chromatograph paper is treated with a solution of a triglyceride, e.g., triolein, tristearin, in a volatile solvent. The solvent is removed, an ethanolic solution of higher fatty acids is applied in the usual manner and the chromatogram is developed with ethanol containing water, which prevents solution of the stationary phase. The chromatogram is then treated with AgNO_3 solution, giving rise to Ag salts of the fatty acids which are insoluble in water, thus allowing excess reagent to be readily removed. Dilute ammonium sulphide solution is applied; this shows the positions of the fatty acids as black spots. Other substances (chloronaphthalene, iodobenzene) can be used as the stationary phase and other alcohols (methanol, propanol) as the mobile phase.—G. A. Garton.

64

VAN DE KAMER, J. H. Quantitative determination of the saturated and unsaturated higher fatty acids in fecal fat. *Scand. J. Clin. Lab. Invest.*, 1953, **5**, 30–36. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

A quantity, 5 to 20 g., of wet faeces from a 24-hr. sample is saponified with ethanolic KOH and the unsaponifiable matter is removed with light petroleum. HCl is added to liberate the fatty acids, which are extracted with light petroleum. After a rough titrimetric estimation of the fatty acid content, a volume of light petroleum solution containing about 0.5 m. equiv. fatty acids is exactly neutralised with 0.1 N ethanolic NaOH, using thymol blue as indicator. The solvents are removed, leaving the Na soaps, the iodine value of which is estimated. Taking 282 as the average mol. wt. of unsaturated fatty acids and 270 as that of

the saturated acids, the amounts of each excreted per 24 hr. can be calculated.—G. A. Garton.

65

KIBRICK, A. C. and SKUPP, S. J. Colorimetric method for the determination of fatty acids in blood by oxidation with dichromate. *Arch. Biochem. Biophys.*, 1953, **44**, 134–139. [Dept. Chem., Coll. Med., Univ. New York.]

A light petroleum extract of blood fatty acids, prepared by Bloor's method (*J. Biol. Chem.*, 1939, **82**, 273) is evaporated to dryness in a test tube. To the tube are added 2 ml. of N potassium dichromate and then 4 ml. of concentrated H_2SO_4 . After mixing, the tube is heated for 20 min. in a pressure cooker at 15 lb. pressure and the cooled contents are made up to 10 ml. The optical density is measured at 600 m μ . and the concentration of fatty acid is calculated by reference to a standard curve. The standard curves for 0.2 to 1.5 mg. amounts of oleic and palmitic acids are almost identical.—G. A. Garton.

66

HERB, S. F. and RIEMENSCHNEIDER, R. W. Spectrophotometric micromethod for determining polyunsaturated fatty acids. *Anal. Chem.*, 1953, **25**, 953–955. [E. Reg. Res. Lab., Philadelphia, Pa.]

An accurately weighed sample, 1 to 10 mg., of fat is introduced into a tube containing 5.0 g. of 21 per cent. KOH in ethylene glycol and the tube is heated in a bath at 180° C. for 15 min. The tube is then rapidly cooled and the isomerised mixture is diluted with absolute methanol before measurement of the extinction coefficient at the appropriate wavelength in a Beckman spectrophotometer. By this method the estimation of linoleic, linolenic, arachidonic and pentaenoic acids gave good reproducibility and good agreement with similar macro-methods employing 100 mg. fat.—G. A. Garton.

67

HANSEN, R. P. and COOKE, N. J. The isolation of lauric acid from butter fat. *J. Sci. Food Agric.*, 1953, **4**, 351–352. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Methyl ester fractions, derived from butterfat and calculated from saponification equivalents to contain a preponderance of lauric acid, were bulked and fractionated chromatographically. Fractions with saponification equivalents approximating to that of lauric acid were converted to fatty acids and crystallised from different solvents at low temperatures to yield *n*-dodecanoic (lauric) acid, which was characterised by elementary analysis, X-ray long spacing and the preparation of suitable derivatives.—G. A. Garton.

CAMA, J. S., CHAKRABARTY, M. M., HILDITCH, T. P. and MEARA, M. L. **The separation of glyceride concentrates from natural fats by crystallization from solvents.** *J. Sci. Food Agric.*, 1953, **4**, 321-328. [Univ. Liverpool.]
Artificial fat mixtures of approximately known composition were prepared from concentrates of different types of mixed glycerides, including palmitostearins (trisaturated), oleopalmitostearin, oleodipalmitin, and oleodistearin (disaturated-monounsaturated), palmitodiolein and steardiolein (monosaturated-diunsaturated) and oleolinoleins (triunsaturated).
Each mixture was systematically crystallised from 10 per cent. solution in acetone at low temperatures, starting at -60° or -70° C.; the temperatures of succeeding crystallisations of deposited solids were gradually raised until crystallisations at 0° C. and above were undertaken. In this way a considerable number of glyceride fractions were obtained, each of which was analysed for component fatty acids.
The results, in general, accorded well with the proportions of glycerides known to be present. In addition, the trisaturated glyceride content of a fat was the same whether it was estimated by crystallisation or chemically by permanganate-acetone oxidation of the unsaturated components. Further, the amount of simple triglyceride, saturated or unsaturated, present in seed fats was directly related to the proportion of the fatty acid concerned in the total fatty acids of the fat.

HULLIN, R. P. and NOBLE, R. L. **The determination of lactic acid in microgram quantities.** *Biochem. J.*, 1953, **55**, 289-291. [Dept. Biochem., Univ. Leeds.]
A modification of the method of Barker and Summerson (Abst. 831, Vol. 11) is described, by means of which from 1 to 8 μg . lactic acid can be estimated within 2 per cent. With slight modification it can be used for the estimation of lactic acid in the presence of pyruvic acid. The protein-free solution under investigation is treated with copper sulphate and lime and the supernatant is shaken with more $CuSO_4$ and H_2SO_4 , heated at 60° C., treated with a *p*-hydroxydiphenyl reagent and incubated at 28° to 30° C. The resulting violet colour is measured spectrophotometrically.
H. G. Bray.

KOTTMEYER, G. Fehlermöglichkeiten bei der Bestimmung kleinster Milchsäuremengen. [Sources of error in the estimation of very small quantities of lactic acid.] *Biochem. Ztschr.*, 1953, **324**, 160-164. [Med. Akad., Justus-Liebig-Hochsch., Giessen.]

In the method previously described (Abst. 89, Vol. 22), several points have been investigated further. The oxidation with KMnO_4 in presence of MnSO_4 cannot be replaced by other procedures. The distillation should be in a current of N_2 , since the O_2 of the air causes loss of acetaldehyde. Titration errors can be avoided only if, in an acid medium, the bisulphite solution is added to the I solution, and not vice versa. Only this procedure gives a quantitative oxidation of the sulphite to sulphate. The magnitude of the blank analysis depends on the method of titration and oxidation, and on the purity of the reagents. Approved methods for deproteinisation are indicated.—M. B. Richards.

78

TURNOCK, D. Paper chromatography of keto-acids. *Nature*, 1953, **172**, 355–356. [Dept. Surg., Univ. Liverpool.]

In testing the specificity of the method of Friedemann and Haugen (Title 16, Vol. 13) for the estimation of blood pyruvic acid, chromatograms of the hydrazones from blood were run with the hydrazones of pyruvic acid, phenylpyruvic acid, α -ketoglutaric acid, acetoacetic acid and acetone. The average R_F values at room temperature for the hydrazones of these keto-compounds, in the above order, were 0.58, 0.84, 0.12, 0.60 and 1.00. The hydrazones of blood always gave 4 spots, 2 corresponding to pyruvate hydrazone, and 2 smaller, faster-running spots, which were identified as phenylpyruvate hydrazone. Blood analysed by the method of Cavallini (Abst. 1729, Vol. 19) showed, in addition to those 4 spots, a spot corresponding to α -ketoglutaric acid and a suspicion of 2 other spots with R_F values 0.44 and 0.73. It appears, therefore, that the method of Friedemann and Haugen allows separation of pyruvate with some phenylpyruvate from the other keto-acids in blood, in a way more specific than the method of Cavallini.

The sample is ashed, the ash is dissolved in HCl and the Ca is precipitated as oxalate. This is mounted on a fritted glass disc by filtration under carefully controlled conditions. After counting, the precipitate is dissolved in HClO_4 and total Ca is estimated by titration with hexanitrate-ammonium cerate, with Setopaline C as indicator.

H. G. Bray.

- COMAR, C. L., MONROE, R. A., VISEK, W. J. and HANSARD, S. L. **Comparison of two isotope methods for determination of endogenous fecal calcium.** *J. Nutrition*, 1953, **50**, 459-467. [Univ. Tennessee-Atomic Energy Comm., Agric. Res. Program, Oak Ridge.]

Endogenous faecal Ca has been estimated in cattle by an isotope dilution method (Abst. 804, Vol. 24). The results were compared with those

obtained by a comparative balance method which is described and discussed. It depends upon a knowledge of the proportion of ingested ^{45}Ca which does not take part in metabolic exchange with stable ions and is excreted in the faeces, and upon estimations of total faecal Ca and faecal ^{45}Ca when ^{45}Ca is included in the diet. The major assumption made is that the source of labelled Ca is absorbed to the same degree as other dietary Ca.

The mean daily endogenous faecal Ca from a group of cattle was 5.7 ± 0.51 g. for the first method and 5.2 ± 0.53 g. for the second.—R. Hill.

- HARRISON, G. E. and RAYMOND, W. H. A. **The determination of microgram amounts of calcium.** *Analyst*, 1953, **78**, 528-531. [Med. Res. Counc., Radiobiol. Res. Unit, Atomic Energy Res. Establishment, Harwell, Didcot, Berks.]

The method is based on the precipitation of Ca as its molybdate, which is separated by centrifuging and converted to molybdenum thiocyanate. This is extracted with isoamyl alcohol and estimated absorptiometrically. The method is particularly useful for estimating Ca in serum from young children or small laboratory animals. As little as $4 \mu\text{g}$. Ca can be estimated to within ± 10 per cent. The presence of phosphate, ferric or ferrous Fe, Mg, Cu or Al does not affect the estimation.—W. Godden.

- RIETHMÜLLER, H. U. and BRETSCHNEIDER, A. **Zur Fehlerbreite der flammenphotometrischen Calcium - Bestimmung in menschlichen Serum (und Urin). [On the range of error in the estimation of calcium in human serum (and urine) by the flame photometer.]** *Hoppe-Seyler's Ztschr.*, 1953, **293**, 49-62; *Klin. Wochenschr.*, 1953, **31**, 527-528. [Med. Klin., Univ. Tübingen.]

In considering the suitability of the flame photometer method for serum Ca estimations in routine clinical work, the authors point out that previous estimations of the range of error have

been based mainly on repeated analyses of inorganic salt solutions or of the same serum, without regard to the complexity of the biological material concerned. The method was therefore investigated for its reliability when applied to single analyses of different sera.

Thirty successive estimations, in which the average deviation from the mean was ± 0.9 per cent., showed the consistency of the results obtainable from one serum. But comparison of the results on 500 different sera with the results obtained on the same sera by a reliable acidimetric titration method showed that there was considerable deviation from those obtained chemically. The sera were divided into groups of low, normal and high Ca content, and the deviations were smallest in the normal-Ca group (± 4.5 per cent.), and largest in the low-Ca group (± 6.9 per cent.). These divergent values are due to the changing conditions of the complex substrate under examination. Of 300 different sera which gave normal values acidimetrically, 12.7 per cent. gave values outwith the normal range by the flame photometer method, 6.7 per cent. below and 6.0 per cent. above. The apparatus and procedure used have only a limited applicability for serum Ca estimations, and are not applicable for urinary Ca analyses. The flame photometric results for 100 urines showed deviations of ± 23 per cent. from those obtained chemically.—M. B. Richards.

WILLIAMS, T. R. and MORGAN, R. R. T. **The determination of calcium in plant material by the flame photometer.** *Chem. and Indust.*, 1953, No. 37, 970. [Nat. Agric. Advisory Serv., Wye, Kent.]

A rapid and accurate method is described. The material is ashed with nitric and perchloric acids, the ash is dissolved in water and Ca is precipitated as oxalate under standard conditions. The oxalate is isolated and dissolved in 0.04 N nitric acid and Ca is estimated in the solution photometrically. The results obtained by this procedure agree favourably with those by a macro-volumetric procedure.—H. G. Bray.

135

- UNDERKOFER, L. A., KITTS, W. D. and SMITH, R. L. Soluble cellulose derivatives as substrate for ruminal microorganisms. *Arch. Biochem. Biophys.*, 1953, 44, 492-493. [Iowa Agric. Exp. Stat., State Coll., Ames.]

Cellulose in which 70 per cent. of the anhydro-glucose units had been replaced by the Na salts of carboxymethylcellulose to render the whole molecule soluble was used as substrate to isolate rumen bacteria. Incorporated in a nutrient agar it gives a clear medium which makes it easy to identify and pick off colonies. Fermentation of this substrate by rumen bacteria produces volatile fatty acids, and the addition of toluene allows glucose to accumulate.—A. T. Phillipson.

136

- SUGDEN, B. The cultivation and metabolism of oligotrich protozoa from the sheep's rumen. *J. Gen. Microbiol.*, 1953, 9, 44-53. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

A method of separating large oligotrich protozoa

from rumen contents is described. *Metadinium medium* and a species of *Entodinium* were studied up to 12 days, the longest time of survival. Powdered cottonwool, 50 mg. daily, as sole carbohydrate substrate allowed survival up to 5 days, but the addition of 50 mg. powdered hay daily allowed survival up to 12 days. One-half to two-thirds of the cellulose supplied disappeared in 2 to 4 days. No organic nitrogen was supplied in the media when cottonwool alone was used, so that cultures of cellulolytic bacteria were unlikely to develop, and it is suggested that disappearance was too rapid to be accounted for by bacteria.

The addition of streptomycin, 560 mg. per ml., to cultures removed all bacteria, as was shown by cultural tests, and under these conditions protozoa died off more rapidly, and it is finally concluded that symbiotic cellulolytic bacteria were essential for survival after stored polysaccharide of the protozoa was exhausted. Streptomycin was not toxic to protozoa, for 2 cultures in which streptomycin-resistant strains of bacteria developed lived for 12 days.—A. T. Phillipson.

BRADY, L. W., COOPER, D. Y., COLODZIN, M., McCLENATHAN, J. E., KING, E. R. and WILLIAMS, R. **Blood volume studies in normal humans.** *Surg. Gynecol. Obstet.*, 1953, **97**, 25-32. [Radioisotope Lab., U.S. Naval Hosp., Bethesda, Md.]

The subjects were healthy volunteers or patients awaiting elective surgery. Human serum albumin labelled with ^{131}I was used on 2 groups each of 20 subjects and blood volume was estimated from a single 10 min. sample with corrected haematocrit or from samples taken 10, 20 and 30 min. after injection to give a disappearance curve of ^{131}I extrapolated to a zero time.

The 3-sample method gave the more consistent results, which were significantly lower than those obtained from a single sample. The statistical significance of the difference for total blood volume was doubtful, but the view is expressed that it was genuine and that error arises from the haematocrit even when corrected.

Two estimations in rapid succession were made by the 3-sample method on 7 subjects with ^{131}I -labelled serum albumin and on 12 with Evans Blue. Reproducibility was good with both methods, the ^{131}I method being the better.

Finally, simultaneous estimations by the 3-sample method were made in 25 subjects of plasma volume with Evans Blue and with ^{131}I -labelled serum albumin and of red cell mass with ^{32}P -labelled red cells.

The Evans Blue method gave the highest values for plasma volume and total blood volume, and the ^{32}P method the lowest; the ^{131}I method was intermediate. The results are discussed, and it is concluded that the most accurate method of estimating total blood volume is by independent estimations of red cell mass with ^{32}P and of plasma volume with ^{131}I , avoiding the use of the haematocrit. Further studies, including estimation of red cell mass with ^{51}Cr , are in progress.—W. M. Deans.

SCHWAB, M. **Zur Methodik der Plasmavolumenbestimmung mit T-1824 ("Evans Blau").** [Technique of estimation of plasma volume with T 1824, Evans Blue.] *Arch. exp. Pathol.*

Pharmakol., 1953, **218**, 251-261. [Med. Klin., Univ. Göttingen.]

To compare the method of Gibson and Evans (Title 1914, Vol. 7) with that of Crooke and Morris (*J. Physiol.*, 1942, **101**, 217), estimations of plasma volume were made on 14 healthy subjects and on 9 patients with cardiac insufficiency. For unclouded and non-lipaemic plasmas the error in the direct photometric estimation by the method of Gibson and Evans was about half as great as that by the method of Crooke and Morris. In turbid and lipaemic plasmas, however, the direct photometric estimation of the concentration of Evans Blue is not possible, and then the method of Crooke and Morris can be used with advantage.

- ROWLANDS, E. N., HONOUR, A. J., EDWARDS, D. A. W., and CORBETT, B. D. **Metal-capsule optical manometer for measuring pressure in the human gut with an open-ended tube.** *Clin. Sci.*, 1953, **12**, 299-306. [Dept. Clin. Res., University Coll. Hosp. Med. Sch., London.]

The use of 1 mm. polythene tubing to record pressure changes in the duodenum is described. The tubing was used either with an open end which was dilated or with a small balloon attached to the end. With both methods the system is air-filled and is attached to a thin-walled brass capsule, the curvature of which alters with the pressure of air in the polythene tubing. A mirror is fixed eccentrically to the capsule and its movements are recorded optically. This method has proved a great deal more sensitive than conventional methods of recording changes of intraluminal pressure in the intestine.

The methods for iodising finely ground salt are not suitable for treating the coarsely crystalline product obtained by solar evaporation in open pans. Equipment is described by which 5 tons daily of coarse salt may be iodised by a mixture of KI or KIO₃ with CaCO₃. With a larger form output could be 25 tons daily. If the salt is to be stored in a humid environment and if KI has been used small quantities of Na₂CO₃, starch, Na thiosulphate or Ca stearate may be added for stabilising, but with KIO₃ this is unnecessary.

- IRVIN, H. M., WISEMAN, H. G., SHAW, J. C. and MOORE, L. A. **The role of plant pigments in digestion trial studies.** *J. Animal Sci.*, 1953, **12**, 541-551. [Dairy Dept., Univ. Maryland, College Park.]

Samples of hay and the faeces of two cows obtained in a digestibility trial were extracted

with 80 per cent. ethanol. The pigments were obtained from these extracts by extraction with light petroleum after dilution to varying concentration with 4 per cent. NaCl. The absorption curves of the pigments obtained were compared in a Beckman spectrophotometer. Chlorophyll, though definitely changed, may remain identifiable in the digestive tract in sufficient quantity to act as a marker. Whilst composite curves of the total hay and total faeces pigments are practically identical and show an average recovery of 97.4 per cent. of the pigments in the faeces and therefore tend to support the basic theory of the chromogen marker technique, it is clear from the results that no one of the pigments alone can be relied upon as a digestion trial marker.—D. M. Walker.

- WHITEMAN, J. V. and WHATLEY, J. A. **An evaluation of some swine carcass measurements.** *J. Animal Sci.*, 1953, **12**, 591-596. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

Measurements of sp. gr., thickness of back fat, area of lean in eye muscle and ham, both by product of length and width and by planimeter, and the percentages of chilled carcass weight of loin, ham and loin and ham together were made on the carcasses of 203 pigs, mainly Duroc and Duroc crosses. Estimation of eye muscle area from the product of length and width was simpler than by planimeter, and almost as accurate. This, com-

bined with sp. gr., was a useful way of predicting leanness of carcase. Average thickness of back fat also gave a good indication of the percentage lean cuts in the carcase.—T. D. Bell.

- CATEL, W., PENDL, J. and SCHIFF, O. Eine neue Methode der Haltbarmachung von roher Frauenmilch. [A new method for preserving raw human milk.] *Deutsch. med. Wochenschr.*, 1953, 78, 1137–1140. [Landeskinderheilstätte Mammolshöhe.]

The disadvantages of preserving human milk by heating are briefly recalled. A satisfactory powder, easily transportable and readily reconstituted with distilled water, may be prepared by freeze-drying [no details of the process are given].

Comparative tests on a batch of fresh human milk divided into 4 portions, untreated, heated in a water-bath at 100° C. for 10 sec., freeze-dried and reconstituted with distilled water, and the same heated at 100° C. for 10 sec., showed that reconstituted freeze-dried milk retained the power of the fresh milk to inhibit the growth of the diphtheria bacillus and *Streptococcus haemolyticus*. A subsidiary experiment indicated that the antibacterial properties are associated with the milk fat. Freeze-drying did not affect the riboflavin, vitamin B₁₂ or vitamin C content, but carotene and vitamin A were reduced more by freeze-drying than by heating. Freeze-dried milk, unlike heated milk, retained the catalase activity and most of the lipase activity, and, for some unknown reason, its amylase activity was twice that of fresh milk.

A later paper will deal with the stability of freeze-dried human milk and details of the organisation of a milk bank based on its use.

- PATTON, S. and JOSEPHSON, D. V. Methionine—origin of sunlight flavor in milk. *Science*, 1953, 118, 211. [Pennsylvania Agric. Exp. Stat., State College.]

Vol. 24, No. 1

Milk containing added methionine at rates of 0, 4, 20 or 50 mg. per qt. was exposed to sunlight in ordinary glass milk bottles for 1 hr. The "sunlight" flavours developed were rated slight, strong, very strong and very strong plus, respectively. A control sample containing 50 mg. methionine per qt. milk developed no flavour when stored in a refrigerator. Addition of riboflavin, 1.5 mg. per qt., to a distilled water solution of methionine, 20 mg. per qt., produced a "sunlight" flavour even in the refrigerated control. Cystine and cysteine added to milk exposed to sunlight had no effect on flavour. The flavour appeared to result from photolysis of methionine.

WHITE, P. L., HEGSTED, D. M. and MAYER, J. **Two complex salts of choline and copper chloride and their activity as catalysts of fat oxidation.** *J. Amer. Chem. Soc.*, 1953, **75**, 2352-2354. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

When choline chloride and copper nitrate are dissolved separately in 95 per cent. ethanol and the solutions are mixed a yellow and a red compound are formed. The former can be extracted by boiling ethanol, from which bright yellow needles are deposited on cooling. The yellow has the formula $((CH_3)_3NC_2H_4OH)_2CuCl_4$ and the red $((CH_3)_3NC_2H_4OH)CuCl_3$. Both substances are hygroscopic. In the absence of moisture they are superior to $CuCl_2$ and $CuSO_4$ as catalysts in the oxidation of maize oil. They are probably responsible for the rapid development of rancidity in experimental diets rich in copper salts and choline.—W. Godden.

175

HARTMAN, L. **Non-toxic stabilizers for animal fats.** *J. Sci. Food Agric.*, 1953, **4**, 430-433. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Data are given on the stabilising effect of mixed glyceryl esters of citric acid and fatty acids on beef and mutton fats and on lard, and their use is suggested as a convenient method of incorporating citric acid in fats. The widespread approval granted by the laws of Britain and western European countries to the use of citric acid and the facts that such esters form true solutions with fats and are effective stabilisers favour their use in this connection.—D. Harvey.

176

WANG, H., ANDREWS, F., RASCH, E., DOTY, D. M. and KRAYBILL, H. R. **A histological and histochemical study of beef dehydration. 1. Rate of dehydration and structural changes in raw and cooked meat.** *Food Res.*, 1953, **18**, 351-359. [American Meat Inst. Found., Univ. Chicago, Ill.]

The results of preliminary histological and histochemical studies on raw and pre-cooked strips of beef muscle (*Biceps femoris*) dehydrated at 70° C. in a convection oven or at 65° C. in a vacuum oven for periods from $\frac{1}{2}$ to 24 hr. are reported.

Pre-cooked meat lost moisture more rapidly and completely than raw meat. Strips cut perpendicular to the muscle fibres lost more moisture than strips cut parallel to them. With raw meat, moisture loss and decrease of muscle fibre diameter ran parallel. Longitudinal striations disappeared and cross striations became less distinct. The only chemical change established was a movement of potassium to the periphery of the fibres.

The strips did not rehydrate satisfactorily when held in water at 70° C. for 15 min.—W. M. Deans.

177

SIEMERS, L. L. and HANNING, F. **A study of certain factors influencing the juiciness of meat.** *Food Res.*, 1953, **18**, 113-120. [Sch. Home Econ., Univ. Wisconsin.]

Methods of small scale cooking and of estimating losses in the process were evolved. Blended samples of lean meat and kidney fat were mixed, with the lean forming 100, 75 and 50 per cent. of the mixtures, and 5-g. samples were treated in a manner simulating braising at temperatures of 70°, 80°, 90° and 98° C. for 5, 10, 20 and 30 min. The complete data are recorded elsewhere (Siemers, *Thesis*, Univ. Wisconsin, 1952); only illustrative curves and summary tables showing statistical findings are reproduced here. Loss of the water phase from blended samples decreased with increasing percentage of fat, and juice loss increased with time of cooking.

In a second experiment rectangular blocks of beef muscle as such or covered with suet were cooked to represent simmering for 10, 15 or 25 min. and losses and effect on palatability were compared. The rate of heat transfer in similar samples was also measured. Increase of length of treatment increased cooking loss, but covering with suet lessened it. The heat transfer rate was less in covered than in uncovered samples and the smaller loss was probably the result of this reduced degree of cooking. Palatability decreased significantly with increasing juice loss.

More detailed study of suet alone showed that the presence in it of connective tissue strands decreased the heat penetration rate compared with that in similar samples which had been minced or from which such tissue had been removed.—D. Harvey.

178

SWANSON, M. H. and SLOAN, H. J. **Some protein changes in stored frozen poultry.** *Poultry Sci.*,

N.A. and R., January 1954

1953, **32**, 643-649. [Dept. Poultry Husb., Univ. Minnesota, St. Paul.]

Ten New Hampshire fowls were killed at 11 to 12 months of age and after dressing were stored at -5°F. for over 40 weeks. Samples of breast and leg meat were taken from each bird at 8-week intervals for the estimation of dry matter, total N, water-soluble N, soluble α -amino-N and soluble N.P.N. Breast muscle had a higher N content than leg muscle throughout and no change in the total N content of either was found in this trial. Water-soluble N increased 13.5 per cent. in leg meat and 14.3 per cent. in breast meat and N.P.N. increased 22.4 per cent. and 27.9 per cent., respectively. These results were taken to indicate proteolysis during storage. The free α -amino-N, however, decreased during storage, indicating that N catabolism continued beyond the amino stage.

M. J. Head.

179

NASH, A. M., MAYFIELD, H. L. and ODLAND, L. M. **Physical, chemical and cooking qualities of eggs as affected by five methods of home preservation.** *Poultry Sci.*, 1953, **32**, 275-284. [Dept. Home Econ., Agric. Exp. Stat., Montana State Coll., Bozeman.]

Clean eggs were treated daily as brought in from the farm. The methods of preservation were (1) in waterglass, 1 part sodium silicate to 9 parts water, (2) by freezing, one tablespoonful of sucrose being mixed with each cup of liquid whole egg before freezing and storage in pint cartons at -10°F. , (3) by a thin coating of creamy emulsion preservative applied to the egg, (4) by oiling, the eggs being dipped at room temperature into mineral oil of Saybolt universal viscosity of 50 to 60 sec. at 100°F. and then drained for 1 hr. and placed in cartons, (5) by plastic coating (*cf.* Yushok and Romanoff, Title 1829, Vol. 19) applied by hand, (6) no treatment. All eggs were stored in the dark at 50° to 60°F. and tested before preserving and after 3 and 6 months' storage. The quality of the eggs was judged on the basis of loss in weight during storage, height, width, index and pH of albumin; colour and height of yolk; palatability of cooked yolk and suitability for poaching and for making baked custards and sponge cakes. The ranking was then fresh, 3, 1, 4, 5, 6. The frozen eggs, 2, could not be included in all the tests because they were broken in storage, but in tests in which comparison was possible freezing ranked third.—M. J. Head.

180

BOTHMA, F. and GREUP, D. H. De houdbaarheid van brood. [**Keeping quality of bread.**] Repr. from *Conserva*, 1952-53, **1**, 406-413. [Centraal Inst. Voedingsonderzoek T.N.O., Wageningen.]

Vol. 24, No. 1

Keeping quality of bread is of little moment in everyday housekeeping and even less for wheat than for rye bread. But it is of great importance for expeditions and in time of emergency. Baking is not always sufficient to sterilise; for instance, the spores of the bacillus that causes rosy bread are not killed. Reduction of pH by sour-dough or addition of lactic or acetic acid helps, but acetic acid and acetates are at present prohibited. Cut bread, especially rye bread, presents a special problem. It may be sterilised by ultraviolet light, or packed and sterilised in the oven. Canned bread becomes increasingly popular in America. Protection from insect, mite and rodent attack is a simple question of suitable packing and storage, or both.

Chemical changes and development of rancidity or bitterness in oat products, and loss of aroma, off-flavours and browning in canned bread can to some extent be avoided by storage at low temperatures. Physical changes such as loss and absorption of water and "staling" are not easily controlled. Staling appears to be due to changes in the starch molecule. It may be reduced by the use of shortening, malt and, more recently, enzymes from fungi or by baking in two stages, with storage in the refrigerator in the interval. Polyoxyethylene stearate is forbidden in the Netherlands.

GORDON, A. L., JENNESS, R. and GEDDES, W. F. **Further studies of the heat-labile loaf volume depressant of milk serum proteins.** *Cereal Chem.*, 1953, **30**, 213-221. [Minnesota Agric. Exp. Stat., St. Paul.]

A study of the fractions of serum milk proteins indicated that the constituent responsible for change in loaf volume was present mainly in the lactoglobulin fraction. Euglobulin and pseudoglobulin prepared from colostrum, which comprise 40 per cent. of this fraction, have been proved to be without effect on loaf volume (Abst. 1396, Vol. 23). The active constituent, still unidentified, is therefore in the remaining 60 per cent. The depression of loaf volume was produced by only 125 mg. protein per 100 g. flour. Further studies are in progress.—D. Harvey.

FRAZER, A. C., MEREDITH, P. and SAMMONS, H. G. **Studies on the effects of chlorine dioxide on gluten.** *Biochem. J.*, 1953, **54**, xxxvii. [Dept. Pharmacol., Univ. Birmingham.]

183

LINDBERG, J. E. Versuch über die Wärmehandlung von Weizen. [**Heat treatment of wheat.**] *Getreide und Mehl*, 1953, **3**, 17-22. [Svalöf.]

Varieties of wheat from 2 seasons' crops were examined. Samples before or after partial air drying were heated in a rotating cylinder in a closed container, in such a way as to avoid further loss of moisture, at temperatures from 35° to 65° C. for a constant time. The effects on the germinating power of the grain and the baking quality of the flour, with or without addition of bromate, were examined.

Germinating power remained unchanged with rise in pre-heating temperature until a critical temperature was reached, when a further rise of 2° to 5° C. caused a sudden fall to zero. The riper the wheat, the higher the critical temperature. In the baking trials leavening capacity and bread weight were, as a rule, unaffected by pre-heating temperature, but bread volume, form, porosity and appearance were much changed. The lower temperatures had little effect on bread volume, but higher temperatures reduced it. If the flour was treated with bromate before baking the effect occurred at lower original temperatures, and with moist wheat this was noticed at the lowest temperature used, 35° C. Changes in volume, shape and porosity were equally dependent on the moisture content of the wheat. Without addition of bromate to the flour critical temperatures for such changes were 50° C. with 25 per cent. moisture, 55° C. with 20 per cent. and 65° C. with 15 per cent. The critical temperatures were 5° to 10° C. lower if bromate was added to the flour.

RENNER, R., CLANDININ, D. R., MORRISON, A. B. and ROBBLEE, A. R. **The effects of processing temperatures on the amino acid content of sunflower seed oil meal.** *J. Nutrition*, 1953, 50, 487-490. [Poultry Div., Univ. Alberta, Edmonton.]

Four sunflower seed meals were examined. The temperatures in the cooker and processor were 240°, 260°; 200°, 220°; 220°, 240° F. for 3 of them. The fourth meal was prepared by autoclaving the second at 15 lb. steam pressure for 4 hr. The essential amino-acids were liberated either by acid hydrolysis (alkaline for tryptophan) or by enzymic hydrolysis. Less lysine, arginine and tryptophan were liberated by chemical hydrolysis from the first than from the second and third meals. Autoclaving the second meal depressed the liberation of these amino-acids. No relation existed between the liberation of essential amino-

acids by enzymic hydrolysis and the relative nutritive values previously reported by Morrison *et al.* (Abst. 5284, Vol. 23).—F. C. Aitken.

ANDERSON, E. E., ESSELEN, W. B. and FELLERS, C. R. **Noncaloric sweeteners in canned fruits.** *J. Amer. Dietetic Assoc.*, 1953, 29, 770-773. [Dept. Food Technol., Univ. Massachusetts, Amherst.]

Raspberries, cherries, blueberries, peaches, pears and rhubarb were canned in sucrose syrup or a solution of saccharin or Sucaryl sodium (cyclohexylsulphamate sodium) of equal sweetness, or water, stored at room temperature and examined by a tasting panel at intervals up to 1 year. All packs had ascorbic acid added to prevent colour changes.

The differently sweetened products were judged almost equally acceptable. All were preferred to the unsweetened. It was found that pectin, sodium carboxymethylcellulose, or Krim-Kold, a seaweed extractive, could be added to saccharin and Sucaryl sodium packs to produce a syrup of viscosity equal to that of sucrose syrup. Since replacement of a 30° Brix sucrose syrup by saccharin or Sucaryl sodium solution reduced the soluble solids (carbohydrate) content and energy value by at least 50 per cent., it is considered that fruit canned with these sweeteners would appeal both to diabetic persons and to those wishing to reduce their weight.—W. M. Deans.

MUKULA, J. Perunan varastomistappioista ja niiden ehkäisemisestä. [Storage losses of potatoes and their control.] *Valtion Maatalouskoetoiminnan Julkaisuja* No. 137, 1953, pp. 39. [Maatalouskoelaitoksen Kasvitaustiasasto, Tikkurila, Finland.] English summary.

Previous work is briefly reviewed. The work reported was done during the 2 seasons 1948 to 1949 and 1950 to 1951.

Losses by rotting were on the average 3 to 4 per cent. during winter storage, i.e., from harvest to April or May. If storage continued to July losses were approximately doubled. High relative humidity did not increase losses, but if the potatoes were wetted rotting occurred more readily, especially if the temperature was high. Fan ventilation of the storage bins decreased the losses. The chemicals Belvitan K, Fusarex, Dormatone, Ipno-germ, Reposine, Tuberite, Mana, Vana, Keim X and Agermine had no effect on loss by rotting.

Losses by sprouting amounted on the average to 10 per cent. by weight of the potatoes by the end of July in untreated samples. Fusarex, Belvitan K and Reposine inhibited sprouting over the same period. Total losses, by rotting and sprouting, in potatoes treated with chemicals increased on the average by 1.3 per cent. per month from 4 per cent. in January to 13 per cent. by the end of July. From harvest to May losses in untreated potatoes were about the same, but after that date losses increased by 7 per cent. per month and amounted to 30 per cent. by the end of July. (From summary.)—P. C. Jowsey.

MÜNCHOW, S. and QUENSTÄDT, J. Beitrag zur Klärung von Lebensmittelvergiftungen und zur Verwendbarkeit von Nickelkochkesseln. [Food poisoning and the use of nickel cooking vessels.] *Zentralbl. Bakteriol. Parasitenk.*, 1953, **159**, 362-371. [Bezirks Hyg. Inst., Chemnitz.]

An outbreak of food poisoning which affected about 250 persons in a hospital was associated with consumption of a goulash prepared and cooked in a nickel pan and re-heated after standing in the pan overnight. The sauce was acid and corrosion of the pan had occurred. There was also a considerable content of mixed bacteria.

The solubility of Ni in vinegar and acid sauces was investigated and considerable amounts of Ni were found in mixtures exposed to the metal for longer than 4 hr. The actual amounts of Ni were probably not poisonous but with prolonged keeping

Vol. 24, No. 1

in the pans there was increased bacterial contamination by "unspecific" organisms. It is recommended that acid foods cooked in Ni pans should be removed from the pans if they must be kept for more than a few hours.—A. M. Copping.

ERIKSSON, S. Kofasaltets verkan som tillsatsmedel vid ensilering av vallfoder. [Effect of Kofasalt for ensiling pasture.] *Kgl. Lantbruksakad. Tidskr.*, 1953, **92**, 213-219. English summary.

Kofasalt is a mixture of 20 parts calcium formate and 3 parts sodium nitrite. As the silage ferments, the salt is supposed to liberate oxides of N which inhibit putrefaction of protein but not lactic acid fermentation. Two series of experiments are described in which 22 kg. alfalfa cut before or at budding stage were ensiled with 66 g. Kofasalt. Each series included duplicate lots ensiled fresh, 18 to 19 per cent. dry matter, wilted to about 25 per cent. dry matter and wilted to 32 to 33 per cent. dry matter.

Kofasalt improved the quality of the silage and reduced losses, much more in that from fresh alfalfa than from wilted; indeed, the effect of wilting exceeded that of the salt.—I. Leitch.

MAŚIAKOWA, W., RUDOWSKA-KOPROWSKA, J., SZCZYGIEŁ, A. and JAKUBIEC, T. Próby zastosowania bomby kalorymetrycznej do masowej kontroli wartości energetycznej posiłków. [Experimental use of a bomb calorimeter in the routine examination of the energy value of meals.] *Rocz. Państwowego Zakł. Hig.*, 1953, 23-39. [Dział. Hig. Żywnienia, Warsaw.] Russian and English summaries.

Samples of meals (whole day's meals, dinners and kitchen and table waste) were analysed by the usual chemical methods and net and gross energy values were calculated. The meals were then burned in a bomb calorimeter. From comparison of the results obtained it is suggested that to obtain the gross energy value of meals of average composition it is necessary to subtract about 5 per cent. from the value obtained by bomb calorimeter. Where net values are to be estimated, 8 per cent. should be subtracted. (From summary.) J. S. Thomson.

REVOREDO ALVA, B. O. Valoración del zinc en productos alimenticios. [Estimation of zinc in food products.] *An. Fac. Farm. Bioquím.*, Lima, 1951, 2, 234-238. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

Zn was estimated by the dithizone colorimetric method in 12 Peruvian foods. In products of vegetable origin the contents were, in mg. per kg.: rice 11.35, wheat flour 26.15, "quinua" (*Chenopodium quinoa*) 17.31, pea flour 25.75, French beans 26.56, lentils 28.16 and carrots 1.9. In foods of animal origin, the contents were, in mg. per kg. fresh product: flesh, brains and liver of cow 13.20, 16.85 and 31.13, respectively, pig flesh 17.91, and edible part of "choros" (a kind of cockle) 23.87.—M. B. Richards.

FOODSTUFFS OF ANIMAL ORIGIN

Milk and Milk Products

201

PETERS, F. E. The chemical composition of New Hebridean human milk. *Brit. J. Nutrition*, 1953, 7, 208-211. [S. Pacific Commission, Noumea, New Caledonia.]

Milk was collected during a 4-hr. period from Melanesian women and data are presented for the fat, lactose, protein, ash, Ca and P in 51 samples. There was some evidence that the lactose and Ca contents of the Melanesian samples were less than in the Australian samples with which they were compared and that, with the long continuation of lactation by the Melanesian women, up to 24 months, there was a slight decline in non-fat constituents.—D. Harvey.

202

KUHN, R., GAUHE, A. and BAER, H. H. Über ein N-haltiges Tetrasaccharid aus Frauenmilch. [A nitrogen-containing tetrasaccharide from human milk.] *Chem. Ber.*, 1953, 86, 827-830. [Inst. Chem., Max-Planck-Inst. Med. Forsch., Heidelberg.]

One of the oligosaccharides detected in human milk by paper chromatography (Gauhe *et al.*, *J. Biol. Chem.*, 1953, in the press) was isolated by repeated chromatography on columns of carbon and Celite, eluted with mixtures of ethanol and water and finally crystallised from absolute alcohol. It was dextrorotatory and only slightly sweet and decomposed at 200° to 205° C. Analysis showed that it was a tetrasaccharide with the formula $C_{26}H_{45}O_{21}N$. On acid hydrolysis it gave glucosamine, galactose and glucose, and it contained 2 molecules of galactose and 1 of glucose. The name lacto-N-tetraose is proposed for it.

BARRY, J. M. and ROWLAND, S. J. **Variations in the ionic and lactose concentrations of milk.** *Biochem. J.*, 1953, **54**, 575-578. [Nat. Inst. Res. Dairying, Univ. Reading.]

Lactose, Na, K and Cl were estimated in samples of milk from 38 cows in different stages of lactation. The results showed linear relationships between Na and Cl, Na and K and K and Cl with the very high correlation coefficients + 0.98, - 0.95 and - 0.97, respectively. Regression equations were calculated for each pair of ions. Analysis of serum from blood samples drawn at the time of milking suggested that the composition of all the milk samples studied could result from the mixing, in different proportions, of a milk similar to that produced in early lactation with a fluid differing only slightly in composition from blood serum.

RAY SARKAE, B. C., RYKALA, A. J. and DUNCAN, C. W. **The essential amino acid content of the proteins isolated from milk of the cow, ewe, sow, and mare.** *J. Dairy Sci.*, 1953, **36**, 859-864. [Dept. Agric. Chem., Michigan State Coll., East Lansing.]

The essential amino-acids were estimated microbiologically in the proteins of cow's, ewe's, sow's and mare's milk. The proteins of the milk from cows and from Shropshire, Rambouillet and Hampshire ewes were similar; the proteins of mare's milk had a higher arginine content and those of sow's milk a higher arginine and a lower leucine, tryptophan and valine content than the protein of cow's milk. The significance of these differences was doubtful, since only a small number of animals were used. The similarities in the amino-acid composition were contrasted with the marked differences in fatty acid composition of mammalian milks.—C. Warner.

213

KERIMOV, G. Moloko byuvolitits i produkty ego pererabotki. [Buffalo's milk and products made from it.] *Mol. Prom.*, 1953, **14**, No. 2, 36. [Trest. Maslodel. Prom., Azerbaidzhan SSR.]

Buffalo's milk contains twice as much fat as cow's milk, and also more protein and salts. It is white with a bluish tinge and has a characteristic taste and odour. The butter made from it is distinguished by its salty taste and a slight odour of volatile fatty acids. It is of a thick consistency

and contains more fatty acids of low molecular weight and less unsaturated fatty acids of high molecular weight than butter made from cow's milk. Cheese made from buffalo milk also has a characteristic taste and is very hard. The quality of the butter and cheese can be improved by changes in processing and is affected also by the diet of the buffaloes.—W. Hughes.

214

PHATAK, S. S. and PATWARDHAN, V. N. *Iso-oleic acids in cow and buffalo milk fat.* *Nature*, 1953, **172**, 456–457. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor.]

Ghee prepared from cow and buffalo butter fats was submitted to KMnO_4 oxidation and the dibasic acid fraction was separated by the method of Hilditch and Vidyarthi (*Proc. Roy. Soc. [A]*, 1929, **122**, 552). Ammonium salts of the dibasic acids were subjected to paper chromatography.

The chromatograms revealed the presence of suberic, azelaic, sebacic, undecanedioic and dodecanedioic acids. It was concluded that, in addition to oleic acid, other octadecanoic acids with double bonds at Δ^8 , Δ^{10} , Δ^{11} , and Δ^{12} exist in cow and buffalo butter fats.—G. A. Garton.

215

CAMA, J. S. and MEARA, M. L. *The component acids of milk fats of Balaenoptera physalus (finner whale).* *Biochem. J.*, 1953, **55**, 365–368. [Dept. Chem., Univ. Liverpool.]

Three samples of finner whale milk contained, respectively, fat 54.5, 40.4, 37.1, solids-not-fat 9.9, 4.9, 11.2, water 35.6, 54.7, 51.8 per cent. After saponification no lower fatty acid was found in the steam distillate. The component fatty acids of the whole fat were, in the 3 samples, respectively: myristic 7.1, 7.3, 10.0, palmitic 15.8, 16.6, 17.6, stearic 3.7, 2.9, 3.4, unsaturated acids, C_{14} , 1.0, 2.4, 1.4, C_{16} , 7.9, 6.2, 8.1, C_{18} , 29.7, 29.7, 26.6, C_{20} 18.2, 19.1, 17.6, C_{22} 15.9, 15.0, 15.0 per cent. Comparison with the data of Klem (*Hvålrad. Skr.*, 1935, **11**, 49) for blue whale milk fat and of Hilditch and Maddison (*Abst.* 2889, Vol. 18) for whale blubber showed close agreement for saturated acids. For unsaturated acids agreement was not so good, C_{16} and C_{18} acids being lower and C_{20} and C_{22} acids higher in milk than in blubber. Whale milk fat is more unsaturated than whale blubber, a finding opposite to that reported for the lactating seal (*Abst.* 1715, Vol. 22 and Carden, 1952, *Thesis*, Univ. Liverpool).—D. Harvey.

Eggs

216

EVANS, R. J., BANDEMER, S. L., LIBBY, D. A. and GROSCHKE, A. C. *The arsenic content of*

eggs from hens fed arsanilic acid. *Poultry Sci.*, 1953, **32**, 743–744. [Dept. Agric. Chem., Michigan State Coll., East Lansing.]

Three groups of 20 Rhode Island Red pullets were given an all-mash breeder ration. From the 4th to 14th weeks inclusive, group 2 received 90 g. and group 3, 180 g. arsanilic acid per ton of feed. The eggs from the birds of group 3 always contained most As. The As content of the eggs from both groups reached a maximum at the end of the 7th week of the experiment and then declined, which showed that a tolerance for the element had developed. The highest As content found in any egg was 0.532 p.p.m. As_2O_3 . There was almost no As in eggs laid during the 17th week, when the experiment ended.—M. J. Head.

217

TÄUFEL, K. and POHLOUDEK-FABINI, R. *Verteilung der Citronensäure in Vogeleiern und ihr Verhalten bei der Bebrütung. [Distribution of citric acid in bird's eggs and its behaviour during incubation.]* *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **96**, 397–405. [Inst. Ernährungsforsch., Potsdam, Rehbrücke.]

Colorimetric estimations of citric acid by the pentabromoacetone method in a series of 8 eggs from Leghorn hens showed that of the total citric acid content per egg, taking the average for the series, 73.69 per cent. was contained in the shell, 19.84 per cent. in the yolk and 6.47 per cent. in the white. The range of variation in each part was considerable, in the shell, for example, the average amount of citric acid per egg was 7.06 mg. with a range from 4.00 to 9.09 mg.; in the yolk the range was 1.51 to 2.38 mg., and in the white 0.46 to 0.92 mg. Analysis of single eggs of other domestic birds showed that for the turkey, guinea hen and bantam the greater part of the citric acid was contained in the shell, as in the hen's egg, but for the goose, duck and pigeon the greater portion was within the egg. Incubation tests on hen's eggs showed that during development of the embryo there was endogenous formation of citric acid. The significance of the experimental data is discussed.—M. B. Richards.

219

PALOHEIMO, L. (with HENTUNEN, I., KUKKONEN, I., PALOHEIMO, I., SALMINIITY, S., SIHVOLA, A. and TUOMALA, L.) Über die Zusammensetzung des Körpers der Milchkühe. [**Composition of the body of the milk cow.**] *Acta agral. fenn.*, 1944, **56**, No. 1, 1-63. [Inst. Haustierlehre, Univ. Helsinki.]

Twenty-three cows, 16 Finnish and 7 Ayrshire, of different ages and grades of fatness were slaughtered and submitted to complete mechanical analysis as in standard slaughter trials. In 3 animals organs and tissues were separately analysed for moisture, protein, fat and ash. In the remaining 20 the following fat estimations were made: (1) mesenteric fat attached to or surrounding the intestinal tract and the uterus, (2) kidney fat, (3) adipose tissue of the organs in the chest cavity, (4) udder fat, (5) subcutaneous fatty tissues of the right half-carcase, (6) fat in the flesh of the right half-carcase. From the results of these analyses, using coefficients obtained from the complete analyses of the 3 animals, a clear picture was obtained of the general composition of the body of a cow. The residual fat which was not accounted for by the above estimations was independent of fatness and amounted on the average to 3.7 per cent. of the net weight of the animal, which was defined as the liveweight minus the weight of the contents of the alimentary tract and bladder. This residual fat is termed "constant fat" as distinct from the "reserve fat" estimated in the standard analyses.

Most of the constant fat consisted of bone fat, the difference being only 1.1 per cent. of the net weight. The net weight minus the reserve fat is termed the "fat-poor weight" and deducting from this a certain part of the fat-free flesh the "lean weight" is obtained. The proportion of fat-free flesh ("variable flesh") was calculated on the basis of one very thin animal which contained 38.1 per cent. of flesh which was termed "constant flesh", and no "variable flesh".

For the 23 cows, slaughterhouse refuse represented 10.7 to 33.8 per cent. of the liveweight. From the averages for the Finnish breed the net weight multiplied by 1.25 gave the liveweight. On the net liveweight basis the following percentage ranges were obtained: blood 6.2 to 7.8; skin 6.5 to 10.1; carcase weight, warm, 52.1 to 65.6; bone 10.7 to 19.5; total fat 7.7 to 26.5, fat-free flesh 35.3 to 42.5. The following percentages were calculated on the warm carcase weight: bone 13.6 to 27.7, carcase fat less bone fat 4.4 to 27.1, kidney fat 0.5 to 5.8, subcutaneous fat 0.1 to 6.2, fat-free flesh 56.4 to 74.1. The fat content of the bones was about 20 per cent. and appeared to be uninfluenced by the degree of

fatness of the animal. The fat content of the flesh, with subcutaneous tissue, varied between 4.9 and 26.5 per cent. Of the total body fat 36.9 to 50.8 per cent. was in the body cavity and 47.7 to 62.2 per cent. in the flesh.

Comparison of the results for cows of different degrees of fatness made it possible, by calculation of the different fat and flesh fractions as percentages of the lean weight, to arrive at certain provisional conclusions about the process of fat utilisation or loss of weight in cows. The increases in reserve fat and of fat-free flesh appear to run parallel, but after the cow has become medium-fat, flesh increase falls behind fat increase. The main reserves of fat, the fat in the body cavity and in the flesh, increase the whole time in roughly constant proportion. In the final stages of fattening the increase in kidney fat and especially in subcutaneous fat is proportionately greater than that of total fat.—W. Godden.

DOTY, D. M., WANG, H. and AUERBACH, E. Dehydrated foods. **Chemical and histological properties of dehydrated meat.** *J. Agric. Food Chem.*, 1953, **1**, 664-668. [American Meat Inst. Found., Chicago, Ill.]

A review.

221

GUNSTONE, F. D. and PATON, R. P. **Animal fats. 1. The component acids of deer fat and of camel fat. 2. The component acids of python fat.** *Biochem. J.*, 1953, **54**, 617-621; 621-625. [Chem. Dept., Univ. Glasgow.]

1. Depot fat was extracted from the tissues of a Scottish stag (*Cervus elaphus*) and of a male bactrian camel (*Camelus bactrianus*). The mixed fatty acids of each fat were separated into groups by low-temperature crystallisation from solutions in methanol and acetone. Each group of acids was converted to methyl esters, which were fractionally distilled *in vacuo*. The fatty acid composition of each fraction was then estimated and the composition of the whole fat derived.

Both fats contained palmitic, stearic and oleic acids as major components, together with smaller amounts of myristic, arachidic, tetradecenoic, hexadecenoic, octadecadienoic and octadecatrienoic acids; camel fat contained some higher unsaturated acids also.

2. Fat attached to the intestines of a female reticulated python (*Python reticulatus*) was extracted with acetone. The mixed fatty acids were treated as above.

The major component acids were palmitic 19.7, stearic 10.8, oleic 47.1 and octadecadienoic 10.7 per cent., the latter consisting almost entirely of "seed fat" linoleic acid. Other acids present in

smaller amounts included myristic, arachidic, tetradecenoic, hexadecenoic, octadecatrienoic and higher unsaturated acids.

The results are similar to others previously reported for amphibians and reptiles and support the generalisation that fats of this type are intermediate in composition between the fats of fish and higher terrestrial animals.—G. A. Garton.

SANDOVAL COLMENARES, T. Análisis químico-bromatológico del *Scartichthys Gigas* o "Borracho". [Chemical and bromatological analysis of *Scartichthys gigas* or "borracho".] *An. Fac. Farm. Bioquim.*, Lima, 1951, 2, 271-275. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

A sample of "borracho" purchased in the Lima market was analysed and the results are presented in detail. The energy and nutritive values of borracho compared favourably with those for other common fish. The flesh contained on the average 19.96 per cent. protein on a fresh basis and the fat, 1.64 per cent., contained 9000 I.U. vitamin A per g.

The popular belief that drinking a broth prepared from the flesh of borracho induces somnolence is unfounded.—P. C. Jowsey.

HORTENCIA OLIVEROS, E. Hidrólisis y valoración de amino-acidos indispensables en la proteína de los peces de los ríos peruanos. (Histidina, metionina, tirosina y triptofano.) [Hydrolysis of and estimation of essential amino-acids in the protein of the fish of Peruvian rivers; histidine, methionine, tyrosine, tryptophan.] *An. Fac. Farm. Bioquim.*, Lima, 1951, 2, 239-247. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

Histidine, methionine, tyrosine and tryptophan were estimated in the proteins of 4 species of fish from Peruvian rivers. Histidine was estimated by the Lang modification of the Pauly Weiss method, methionine by the direct colorimetric method of McCarthy and Sullivan, tyrosine and tryptophan by the method of Folin and Ciocalteu. The fish and the percentage contents of the amino-acids in the above order were: paiche (*Arapaima gigas*) 1.38, 4.161, 3.10, 1.62; trucha (*Salmo* sp.) 0.531,

3.404, 2.35, 1.16; bagre (gen. *Pygidium*) 0.353, 3.936, 2.01, 0.73; and carp (*Cyprinus carpio*) 0.622, 3.96, 3.56, 0.68.—M. B. Richards.

225

PALLARDEL PERALTA, T. H. Hidrólisis y valoración de amino-acidos indispensables, histidina y metionina, en la proteína de peces de la costa Peruana. [Hydrolysis of and estimation of essential amino-acids, histidine and methionine, in the protein of fish from the coast of Peru.] *An. Fac. Farm. Bioquim.*, Lima, 1951, 2, 248-256. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

Histidine and methionine were estimated in the proteins of 10 species of fish from the coast of Peru; the methods were as in the preceding Abst. The fish and the percentages of histidine and methionine found were: bonito (*Sarda chilensis*) 1.036, 3.483; borracho (*Scartichthys gigas*) 0.410, 2.615; corvina (*Sciaena gilberti*) 0.387, 3.916; cojinova (*Neptomenus grasus*) 0.473, 1.792; lorna (*Sciaena deliciosa*) 0.496, 1.853; liza (*Mugi peruanus*) 0.633, 3.185; lenguado (*Paralichthys adpersus*) 0.867, 1.270; pejerrey (*Austromenida regia*) 0.709, 3.795; ray (*Dasyatis brevis*) 0.583, 1.353; tollo (*Mustus dorsalis*), 0.594, 2.409.

M. B. Richards.

ZANONI, V., T. Análisis bromatológico de la carne de "Aetobatus Peruvianus" o Raya. [Bromatological analysis of the flesh of *Aetobatus peruvianus*, or ray.] *An. Fac. Farm. Bioquim.*, Lima, 1951, 2, 282-286. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

The flesh of *Aetobatus peruvianus* had the following percentage composition: moisture 75.56, total protein 20.99, fat 0.870, ash 1.979, carbohydrates 0.094, tyrosine 2.288, and tryptophan 1.007. Vitamin A content was 39,700 I.U. per g. fat. The energy value was 92.166 Cal. per 100 g. fresh material. The ash contained: Ca 0.066, P 0.308, Cl 0.115, I 0.0061 g. and Fe 0.743 mg. per 100 g. These characteristics, and its agreeable taste, make it an acceptable food for man.

M. B. Richards.

227

HORNA ACOSTA, B. Estudio bromatológico de la carne del "Geniapterus Maculatus" o Congrio. [Bromatological study of the flesh of *Geniapterus maculatus*, or conger-eel.] *An. Fac. Farm. Bioquim.*, Lima, 1951, 2, 276-281. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

Details are given of the chemical composition of conger-eel flesh purchased in Lima market. The total protein content was 17.63 per cent. on a

N.A. and R., January 1954

fresh basis, of which 15.77 per cent. was digestible. Fat amounted to 2.14 per cent. and contained 16,200 I.U. vitamin A per g. Vitamin D was present but was not estimated.—P. C. Jowsey.

228

VENKATARAMAN, R. and CHARI, S. T. **Studies on mackerel fat variations: correlation of plankton fat with fat of fish.** *Proc. Indian Acad. Sci. [B]*, 1953, **37**, 224–227. [Fish. Technol. Stat., Kozhikode.]

Fat was estimated at monthly intervals for 18 months in the flesh and whole body of mackerel (*Rastrelliger kanagurta*) and in plankton collected in the same fishing grounds. No statistical analysis was made, but it is considered that there is some correlation between the fat contents of plankton and mackerel.—P. C. Jowsey.

229

OLLEY, J. and LOVERN, J. A. **The lipids of fish. 3. The acetone-insoluble fraction of an acetone extract of the flesh of the haddock.** *Biochem. J.*, 1953, **54**, 559–569. [D.S.I.R., Torry Res. Stat., Aberdeen.]

For parts 1 and 2 see Abst 4042, Vol. 23.

It was observed that some of the lipids present in a crude acetone extract of haddock flesh were, after purification, almost insoluble in acetone at 0° C. This material was fractionated by counter-current distribution between light petroleum and 85 per cent. (v/v) ethanol, some of the products being further fractionated according to their solubility in absolute alcohol at –30° C. Two fractions consisting mainly of lecithin and two consisting largely of an unidentified lipid were obtained and submitted to detailed fatty acid analysis. The lecithins differed from those isolated previously from the acetone-soluble fractions of the same total tissue extract. The unidentified lipid contained a higher ratio of fatty acids to glycerophosphate than any known glycerophosphatide. Attention is drawn to certain analytical difficulties which were encountered, particularly the apparent loss of both N and P during the hydrolysis of phospholipins.—W. Godden.

230

SHORLAND, F. B. **New Zealand fish oils. 6. Seasonal variations in the composition of New Zealand groper (*Polyprion oxygeneios*) liver oil.** *Biochem. J.*, 1953, **54**, 673–677. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Samples comprising from 8 to 53 livers were obtained at intervals of about 2 months over the period 1938 to 1943. The livers were weighed and analysed. Some samples of pyloric caeca and intestines were also analysed.

The percentages of vitamin A, cholesterol, total

Vol. 24, No. 1

unsaponifiable matter and phospholipin as well as the iodine value of the liver oil increased significantly just after spawning, when the oil content of the liver was low. The oil content of the pyloric caeca decreased also during September to October, but without the spectacular rise in vitamin A content observed in the liver oil at this period. Vitamin A reserves were concentrated almost entirely in the liver, with smaller amounts in the pyloric caeca. Although the percentage of oil increased with the size of the liver the total vitamin A, cholesterol, total unsaponifiable matter and lipid P in the liver were relatively unaffected.

W. Godden.

231

CANALES, H. **Estudio bromatológico de algunas harinas de pescado. [Bromatological study of some fishmeals.]** *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 257–270. [Lab. Tecnol. Pesquera Callao, Univ. Nac. Mayor de San Marcos.]

Nine samples of fishmeals from factories in Peru were analysed. Protein ranged from 54.25 to 77.00, fat from 6.15 to 22.49, and ash from 6.68 to 27.68 per cent. For use in animal feeding, high protein content and low fat content are the most important points. Fat should not exceed from 7 to 10 per cent.; higher amounts may give a disagreeable smell and taste to the feed, and may cause digestive disturbances. The best meals analysed were a whalemeal and a "machete" meal prepared by one factory. These had protein contents of 77.00 and 57.25 and fat contents of 6.25 and 6.60 per cent. A sample of "bonito" meal and one of "anchoveta" meal from different factories had high protein contents, 59.50 and 62.56 per cent., but contained too high a percentage of fat, 12.72 and 10.49, respectively. Three samples of bonito/atún meal from one factory had fat contents of 19.66, 22.49 and 17.45 per cent., respectively. This indicates some defect in the manufacturing process. It is urged that the factories should aim at producing meals of low fat content. One factory which used liquefied butane as organic solvent obtained fat contents as low as 2.26 per cent.—M. B. Richards.

PENCE, J. W. and ELDER, A. H. **The albumin and globulin proteins of wheat.** *Cereal Chem.*, 1953, **30**, 275-287. [W. Reg. Res. Lab., Albany, Calif.]

A commercial unbleached flour milled from soft wheats was used. Albumins were extracted with

a dilute phosphate buffer and separated from gliadin and pentosans by ammonium sulphate fractionation. The preparation was fairly homogeneous in the ultracentrifuge but heterogeneous on electrophoresis; paper electrophoresis showed at least 6 components. The mol. wt., calculated from osmotic pressure measurements, was 28,000 in dilute saline, but 17,000 in the presence of urea or sodium salicylate. Dialysis of these preparations caused some of the protein to precipitate and the remainder showed a mol. wt. of 28,000 in saline. The total N content was 17.1 per cent., of which 8.3 per cent. was amide N, 2.6 per cent. tryptophan N and 16.3 per cent. arginine N.

Globulins were extracted with *M* NaCl and fractionated with ammonium sulphate. In the ultracentrifuge α - and γ -globulins were found, with a small amount of a substance of high mol. wt. thought to correspond to the δ -globulin previously found in barley but not in wheat. The total N content was 18.6 per cent., of which 6.0 per cent. was amide N, 0.73 per cent. tryptophan N and 29.5 per cent. arginine N.—C. Warner.

239

KURKELA, R., KORHONEN, E., ROSSANDER, M. and ROINE, P. **Suomalaisen leivän fytiinihappopitoisuudesta. [Phytic acid content of Finnish breads.]** *Maataloust. Aikakausk.*, 1953, **25**, 84-92. [Dept. Nutrit. Chem., Univ. Helsinki.] English summary.

Phytic acid P was estimated by the method of McCance and Widdowson (Abst. 4339, Vol. 5) in 60 samples of the 9 commonest types of bread used in Finland and in the corresponding flours, and the results are tabulated. Among the breads, whole wheat and whole barley breads made with yeast retained most, from 120 to 170 mg. phytic acid P per 100 g. dry matter. The phytic acid content of rye bread decreased with increasing acidity and some kinds had very little; more was destroyed by a 3-phase baking process than by a 2-phase. Hard rye bread retained considerably more than soft rye bread of the same acidity.

Average daily consumption of cereals per head in Finland has been estimated to be 315 g.; about 100 g. rye, 50 g. whole wheat, 125 g. white wheat flour, and the rest oats and barley. On the assumption that rye and wheat are consumed as bread and the others as porridge, it was calculated that the daily intake of phytic acid P is about 155 mg. from bread and 75 mg. from porridge. This could bind 240 mg. Ca. Since the cereals themselves contain about 90 mg. Ca, about 150 mg. Ca from other foods might be rendered unavailable; but since the average Finnish diet provides at least 1300 mg. Ca daily, the loss due to phytic acid in cereals is not considered serious. (From summary.)

BRESSANI, R., ARROYAVE, G. and SCRIMSHAW, N. S. **The nutritive value of Central American corns.** 1. Nitrogen, ether extract, crude fiber, and minerals of twenty-four varieties in Guatemala.

AGUIRRE, F., ROBLES, C. E. and SCRIMSHAW, N. S. 2. Lysine and methionine content of twenty-three varieties in Guatemala.

AGUIRRE, F., BRESSANI, R. and SCRIMSHAW, N. S. 3. Tryptophane, niacin, thiamine, and riboflavin content of twenty-three varieties in Guatemala. *Food Res.*, 1953, 18, 261-267; 268-272; 273-279. [Inst. Nutric. Centro América y Panamá, Guatemala.]

1. The results are presented in detail. Average values, range in brackets, were: total N 1.52 (1.09 to 1.92), protein (N \times 6.25) 9.5 (6.8 to 12.0), fat 5.63 (3.80 to 7.62), crude fibre 1.40 (1.0 to 1.8), ash 1.48 (1.08 to 1.85) per cent., P 320 (212 to 424), Fe 3.00 (1.98 to 5.32) mg. per 100 g., all calculated to 10 per cent. moisture content.

2. The results are presented in detail. Average values and ranges, estimated microbiologically, were: methionine 0.14 (0.10 to 0.22), lysine 0.32 (0.28 to 0.40) per cent., calculated to 10 per cent. moisture content.

3. Tryptophan and nicotinic acid were estimated microbiologically, riboflavin fluorimetrically and vitamin B₁ by the thiochrome method. The results are presented in detail. Average results and ranges were: tryptophan 0.046 (0.025 to 0.059) per cent., nicotinic acid 1.77 (1.25 to 2.67), riboflavin 0.08 (0.05 to 0.11), vitamin B₁ 0.52 (0.37 to 0.71) mg. per 100 g., all calculated to 10 per cent. moisture content.—P. C. Jowsey.

KLIMENKO, V. G. **Formy azota semyan i belkov nuta (Cicer arietinum) L. [Forms of nitrogen in seeds and proteins of the chickpea (Cicer arietinum, L.).]** *Biokhimiya*, 1953, 18, 12-18. [Lab. Biokhim. Rastenii, Kishinevsk. Gosud. Univ.]

The effect of variety and year of harvest on the distribution of N in the seeds and proteins of 8 varieties of chickpea was investigated. Total N in seeds grown in the same year ranged from 2.95 to 3.44 per cent. according to variety, and total N for any particular variety varied from year to year. Total S and the percentage of methionine and cystine differed slightly with variety; the year of harvest had a considerable effect on the amounts of S and S amino-acids. The amount of mono-aminodicarboxylic N was independent of variety, but the year of harvest had some effect. There was a considerable intervarietal difference between the lysine contents of the seeds, but the arginine and histidine contents were fairly constant. The results showed the importance of breeding for increased assimilable amino-acids.—W. Hughes.

246

DJANG, S. S. T., LILLEVIK, H. A. and BALL, C. D. **Factors affecting solubilization of the nitrogenous constituents of the Mung bean, *Phaseolus aureus*.** *Cereal Chem.*, 1953, 30, 230-235. [Kedzie Chem. Lab., Michigan State Coll., East Lansing.]

Mung beans were ground to pass sieves of 20, 40 and 60 mesh and samples of from 5 to 15 g.

in 2.5 g. steps were extracted with a constant volume, 100 ml., of 0.4 M NaCl under fixed conditions of temperature, time and agitation. After centrifuging at 2000 r.p.m. for 15 min., protein was estimated in the supernatant liquid.

The solubility of the protein increased with decreasing particle size and with a high ratio of sample to solvent. With 60-mesh meal, extraction was almost complete with either hand or mechanical shaking. By successive extractions, 60, then 10, then 5 per cent. of the N was removed. Below 45° C. the yield of N from lipid-free meal was greater than that from meal containing lipid. Above this temperature the reverse was true.

P. C. Jowsey.

REYNOLDS, H., GILPIN, G. L. and HORNSTEIN, I. **Palatability and chemical studies on peanuts grown in rotation with cotton dusted with insecticides containing benzene hexachloride.** *J. Agric. Food Chem.*, 1953, **1**, 772-776. [Bur. Human Nutrit., U.S. Dept. Agric., Washington 25, D.C.]

Eighty-two samples of groundnuts were collected from areas that had previously carried crops of cotton treated with benzene hexachloride. Peanut butter was prepared and each sample was judged by a trained panel. The results were inconclusive and inconsistencies arose especially when the flavour was at the threshold level. The judges were re-trained before further tests.

Two samples of groundnuts from plots which had carried cotton treated with 3.8 and 5.14 lb. per acre of the γ -isomer were judged to have off-flavours. There was some evidence that the flavour of benzene hexachloride may depend on the form in which it is present, since samples to which it had been added in amounts greater than those in the test samples were rated the same as control samples not containing it.—D. Harvey.

GARCIA SANJUAN, J., VIGUERA LOBO, J. M. and ROYO IRANZO, J. **Approvechamiento de los residuos de la industrialización de los agrios. 5. Estudio químico de los piensos preparados a partir de frutos cítricos Españoles. A. Composición en sus constituyentes fundamentales. [Use of the residues from industrial processing of fruits. 5. Chemical study of feeds prepared from Spanish citrus fruits. A. Proximate composition.]** *Bol. Inst. nac. Invest. agronom., Madrid*, 1953, **13**, 1-27. [Dept. Quim. Vegetal.] French summary.

Of the 16 feeds analysed, 7 were commercially produced from orange residues or whole fruit and the rest were processed in the laboratory from whole oranges (4 samples), whole lemons (3 samples) and whole grapefruit (2 samples). The method of processing varied in minor details, but consisted of grinding, neutralising with lime, pressing and drying, either artificially in a rotary drum drier or by exposure to the air or sun.

The samples were similar in composition and the mean composition of the 16 feeds was: crude protein 7.46, fat 3.42, crude fibre 13.08, ash 6.82, pentosans 17.43, total sugars 14.15, reducing sugars 10.88, pectin 8.91 per cent. on a dry matter basis. The average moisture content was 10.73 per cent.

Removal of the seeds before processing reduced the protein and fat contents; apart from this, the composition of the feed was affected by the species and variety and by the degree of ripeness. Rapid drying of the feed, as in the commercial samples,

N.A. and R., January 1954

reduced losses by fermentation and produced a feed similar in composition to the original material.

HUSKINS, C. W. and SWIFT, L. J. **Storage changes in the phosphorus, nitrogen, and fatty acid constituents of the lipid in canned Florida Valencia orange juice.** *Food Res.*, 1953, **18**, 360-363. [U.S. Citrus Products Stat., Winter Haven, Fla.]

Total N, choline N, amino-N, other N (by difference), total P, total fatty acids and constituent conjugated and non-conjugated acids were estimated in the juice lipid of Valencia oranges before and after 6 and 12 months' storage of the juice in cans.

Over a period of 12 months total N decreased from 0.73 to 0.44 per cent.; choline N was particularly affected, falling from 0.27 to 0.08 per cent. Total P fell from 1.40 to 0.63 per cent. over the same period, most of the loss occurring during the first 6 months. Fatty acids increased over 12 months from 57.55 to 64.24 per cent. The iodine value fell from an initial value of 115.0 to 106.7 after 12 months.—P. C. Jowsey.

[**Chemical and bromatological study of olives (Olea europea).**] *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 219-225. [Lab. Invest., Univ. Nac. Mayor de San Marcos, Lima.]

Green (fresh), dried and brine-stored olives from 3 centres were analysed and the results are presented in detail.

Typical results for samples in the above order were: ether extract 18.65, 56.86, 27.52; protein 2.36, 3.94, 3.36; ash 2.76, 4.01, 6.66 and dry matter 29.24, 75.32, 42.12, all as percentages of the weight of each type of fruit. Carotene contents of the oils were 2.24, 9.44 and 7.1 mg. per g., respectively. The brine-stored samples had a relatively high chloride content, 3.91 per cent., compared with the fresh and dried samples, 1.98 and 0.94 per cent., respectively.

Organoleptic characters of the samples are listed also.—P. C. Jowsey.

FLORES FLORES, A. **Estudio químico-bromatológico del Allium Sativum (Ajo) y Allium Cepa (Cebolla).** [Chemical and bromatological study of *Allium sativum* (garlic) and *Allium cepa* (onion).] *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 229-233. [Lab. Bromatol., Univ. Nac. Mayor de San Marcos, Lima.]

Details of the composition of red and white onions and red and white garlic are presented.

P. C. Jowsey.

260

CHANNING, D. M. and YOUNG, G. T. **Amino-acids and peptides. 10. The nitrogenous constituents of some marine algae.** *J. Chem. Soc.*, 1953, 2481-2491. [Dyson Perrins Lab., Univ. Oxford.]

The chemical distribution of N in *Laminaria saccharina*, *L. cloustoni*, *Ascophyllum nodosum*, *Pelvetia canaliculata* and *Rhododymenia palmata* was investigated.

Peptides and proteins accounted for most of the organic N; small amounts of volatile bases were present and in *L. cloustoni* and *R. palmata* appreciable amounts of free α -amino-acids were detected. Amino-acids were identified chromatographically in hydrolysates of 4 of the seaweeds and some were estimated quantitatively.

A new reagent, 1-bromo-2-fluoro-3:5-dinitrobenzene, was used to estimate the reactive groups in peptides. Full details of techniques are given.

P. C. Jowsey.

261

COULSON, C. B. **Amino-acids of marine algae.** *Chem. and Indust.*, 1953, No. 37, 971-972. [Inst. Seaweed Res., Inveresk, Midlothian.]

Amino-acids occurring free and in peptide form were investigated in the seaweeds *Ascophyllum*

nodosum, *Pelvetia canaliculata*, *Fucus vesiculosus*, *Laminaria saccharina*, *L. cloustoni*, *Rhodomenia palmata* and *Gigartina stellata*. A list of the acids identified in hydrolysed ethanolic extracts of the seaweeds is presented.—P. C. Jowsey.

262

COULSON, C. B. **Proteins of marine algae.** *Chem. and Indust.*, 1953, No. 38, 997-998. [Inst. Seaweed Res., Inveresk, Midlothian.]

Proteins were extracted from dried, milled samples of *Rhodomenia palmata*, *Pelvetia canaliculata*, *Ascophyllum nodosum* and *Laminaria cloustoni* and from fresh samples of *Enteromorpha intestinalis*, *Porphyra umbilicus*, *A. nodosum* and *L. digitata*. After alkaline or acid hydrolysis the amino-acids were identified chromatographically. Lists of the amino-acids found are presented.

Histidine, though present in the fresh seaweeds, was not found in the dried samples. Its absence was thought to be due to drying and/or the method of extraction.—P. C. Jowsey.

263

ROSS, A. G. **Some typical analyses of red seaweeds.** *J. Sci. Food Agric.*, 1953, 4, 333-335. [Dept. Chem., Univ. Edinburgh.]

Pasture, Hay and Silage

264

PETERSON, M. L. and HAGAN, R. M. **Production and quality of irrigated pasture mixtures as influenced by clipping frequency.** *Agronom. J.*, 1953, 45, 283-287. [Dept. Agronom., Univ. California, Davis.]

Four irrigated pasture mixtures were cut at intervals of 2, 3, 4 or 5 weeks over 3 years. Total yields, adjusted to a 12 per cent. moisture basis, increased with the interval between cuttings. The average increase of all mixtures with extension of interval from 2 to 5 weeks was 92 per cent. Percentage increases for ladino and grass, alfalfa and grass, trefoil and grass, and alfalfa and ladino, trefoil and grass mixtures were 43, 177, 90 and 86 respectively. Botanical and chemical analyses were made in the second year. As the cutting interval was extended the proportion of legumes increased, percentage ash, crude protein and ether extract decreased and fibre increased.

It is suggested that mixtures containing ladino clover as the principal legume should be grazed intensively at intervals of 25 to 28 days, but when trefoil or alfalfa is the dominant legume a slightly longer interval should be allowed.—F. C. Aitken.

265

NICHOLSON, H. H., FIRTH, D. H., EDEN, A., ALDERMAN, G., BAKER, C. J. L. and HEIMBERG, M. **The effect of ground water-level**

upon productivity and composition of fenland grass. *J. Agric. Sci.*, 1953, 43, 265-274. [Sch. Agric., Univ. Cambridge.]

For previous work see Abst. 4671, Vol. 21.

The results of the work here reported in general confirmed the conclusions arrived at before. A high water level, about 18 in. below ground level, adversely affected the yield and quality of ryegrass as shown by its protein content. A high water level also depressed the amounts of K and Mg in the grass, but had no consistent effect on Ca and P. P. C. Jowsey.

266

WHISTLER, R. L. and DESZYCK, E. J. **General composition of switchgrass *Panicum virgatum*.** *Arch. Biochem. Biophys.*, 1953, 44, 484-491. [Dept. Agric. Chem., Purdue Univ., Lafayette, Ind.]

267

PIGDEN, W. J. **The relation of lignin, cellulose, protein, starch and ether extract to the "curing" of range grasses.** *Canad. J. Agric. Sci.*, 1953, 33, 364-378. [Exp. Stat., Swift Current, Sask.]

Two native grasses, common speargrass (*Stipa comata*) and rough fescue (*Festuca scabrella*), which "cure" well, were compared with 2 introduced species which do not have this property.

The position and extent of lignification was of greater importance in curing than the total quantity present. No relation was found between protein or starch contents and "curing" ability. P. C. Jowsey.

268

STEWART, A. B. and HOLMES, W. **Manuring of grassland. 1. Some effects of heavy dressings of nitrogen on the mineral composition of grassland herbage.**

RAYMOND, W. F. **2. Use of nitrogen.**

HAMILTON, R. A. **3. Manuring and utilization.** *J. Sci. Food Agric.*, 1953, 4, 401-408; 409-410; 411-414. [Macaulay Inst. Soil Res., Aberdeen.]

1. The results discussed are those obtained from current work, previous reports of which were noted in Absts. 274, 3252, Vol. 19 and 3271, Vol. 21.

Dry matter yield, botanical composition, protein, P, K, Ca, Mg, Na and Mn were estimated in herbage from ryegrass-dominant pasture given heavy dressings of N fertiliser with or without P and K fertilisers.

The results indicated that high yields of herbage with high protein and normal mineral contents can be maintained over a number of years by the application of N, provided that adequate amounts of other major nutrients are given also.

N.A. and R., January 1954

2. Heavy N applications tend to reduce the percentage of clovers in mixed swards, and it is recommended that on the general farm dressings of not more than 4 cwt. Nitro-chalk per acre should be used. Even at this rate the supply of N fertilisers is inadequate to dress more than a small proportion of British grasslands, if allowance is made for the prior demands of other crops such as cereals, potatoes and sugar beet. At present, less than $\frac{1}{2}$ cwt. N fertiliser per acre of grassland is available.

3. Fertiliser dressings for different swards are listed and the effect of time of application is discussed.

The average cost per ton of producing starch equivalent on over 60 farms of different types for which records were kept is given in tabular form.

P. C. Jowsey.

269

BIRCH, H. F. **The relationship in acid soils between base saturation and phosphorus uptake by grasses.** *J. Agric. Sci.*, 1953, **43**, 329-333. [E. African Agric. and Forest. Res. Organiz., Kikuyu, Kenya.]

270

FERGUSON, W. S. and TERRY, R. A. **Purines in grassland herbage.** *Nature*, 1953, **172**, 346-347. [I.C.I., Ltd., Jealott's Hill Res. Stat., Bracknell, Berks.]

The purines adenine, guanine, xanthine and hypoxanthine were almost certainly identified chromatographically in juice from "grassland plants" [species not stated]. They probably exist in the free state but may be formed by the "enzymic breakdown of nucleosides etc."

Tentative chromatographic analysis of another fraction suggested the presence of the pyrimidines thymine and uracil. The work continues.

P. C. Jowsey.

271

DAVIES, R. O., MORGAN, T. B. and DAVIES, W. E. **The yields and composition of lucerne, grass and clover under different systems of management. 1.** *J. Brit. Grassland Soc.*, 1953, **8**, 149-168. [Univ. Coll. Wales, Aberystwyth.]

Alfalfa, grasses and clover were sown in small plots alone and in different combinations. Three cutting managements were used: 4 cuts per season to give a high quality product; 3 cuts as the "normal" management and 2 cuts consisting of hay and aftermath only.

Yields and percentages of dry matter and crude protein and contents of carotene, Ca and P were estimated for each cut. Botanical composition was estimated also. The results are presented in detail.

Maximum dry matter yield was obtained in the

first year by cutting 3 times, but in the second year, from the plots cut only twice in the first season. Similarly, maximum crude protein in the first year was from 3 or 4 cuts, but in the second year from the plots cut twice in the first year. There was no advantage in cutting 4 times in the first season as, apart from the reduction of yields in the second year, the alfalfa plants were exhausted, the stand was weakened and weeds were able to establish themselves more easily.

With alfalfa mixtures, 3 cuts in the first year gave the best results over 2 years, but for long leys it is suggested that 2 cuts only would be the safest management.

Alfalfa alone gave the best results when cut 3 times in each of the 2 years.—P. C. Jowsey.

272

MILLIKAN, C. R. **Relative effects of zinc and copper deficiencies on lucerne and subterranean clover.** *Austral. J. Biol. Sci.*, 1953, **6**, 164-177. [Plant Res. Lab., Dept. Agric., Burnley, Victoria.]

Details and photographs are given of the signs of Zn and Cu deficiencies in plants of subterranean clover var. Dwalganup and of alfalfa var. Hunter River grown in nutrient solution.—P. C. Jowsey.

273

MATHAMS, R. H. and SUTHERLAND, A. K. **The oxalate content of some Queensland pasture plants.** *Queensland J. Agric. Sci.*, 1952, **9**, 317-334. [Chem. Lab., Div. Plant Indust.]

The total and water-soluble oxalate contents of 80 species of pasture plants were estimated. Thirty-four species contained less than 0.5 per cent. total oxalate and 17 species more than 4.0 per cent. Oxalate content was highest in young plants and varied with rainfall and probably also with soil and other environmental factors.

P. C. Jowsey.

274

ASHTON, W. M. and MORGAN, D. E. **The chemical composition and nutritive value of Welsh hay: comparison with other British hays. 2.** *J. Brit. Grassland Soc.*, 1953, **8**, 131-147. [Dept. Agric. Chem., Univ. Coll. Wales, Aberystwyth.]

Ash, Si, Si-free ash, Ca, P, Cl, Mg, Fe, Mn, Cu and Co were estimated in a total of 225 samples of meadow and seeds hays collected from Welsh farms. Individual species were analysed also. The results are presented in detail.

Average values for meadow and seeds hay, respectively, were: ash 6.46, 6.06; Si-free ash 4.79, 4.39; CaO 0.88, 0.93; P₂O₅ 0.50, 0.50; Cl 0.68, 0.68; MgO 0.30, 0.31 per cent.; Fe 135, 119; Mn 122, 88 and Cu 7.4, 6.3 p.p.m., all on a dry matter basis.—P. C. Jowsey.

275

SCHARRER, K., SCHREIBER, R. and KÜHN, H. Über die Zusammenhänge zwischen dem Entwicklungszustand der Luzerne und ihrer Silierfähigkeit. [Stage of growth of lucerne and its suitability for silage.] *Arch. Tierernährung*, 1952, **3**, 160-176. [Agrikulturchem. Inst., Justus Liebig Hochsch., Giessen.]

Alfalfa was cut at 3 stages of growth, before, during and after flowering, and was made into silage with the addition of one of 3 commercial preservatives: crude formic acid, Kofasalt and Glykosil-Streusalz. [The composition of the 2 latter is not given.] The green material was sampled and analysed at each cutting and 300 kg. was put into each silo. The silos were opened and emptied after about 10 weeks and the contents were weighed and analysed. The percentage losses were: organic matter 12 to 13, crude protein 6 to 7, true protein 41 to 50, crude fibre 4 to 9, N-free extract 21 to 25. These figures were not affected in any regular manner by stage of growth at cutting. The use of Kofasalt resulted in much smaller losses of all constituents than when either of the other 2 preservatives was used. The losses of crude and true protein were reflected in a rise in amide N, and there was also a rise in ether extract in the silage with increasing maturity of the original crop. The pH of the silage was below 5 in the first 2 stages of growth with the first 2 preservatives but above 5 with the third, and above 5 at the third stage of growth with all preservatives. Kofasalt gave the best results at all stages of growth and the same was true with respect to ammonia N formation, the relative proportions of lactic and butyric acids in the total volatile acids, and the grading of the silage.—W. Godden.

276

SCHARRER, K., SCHREIBER, R. and KÜHN, H. Silierversuche über die Nährstoffverluste beim Anwelkverfahren. [Silage experiments to test loss of nutrients in the wilting process.] *Arch. Tierernährung*, 1952, **3**, 177-187. [Agrikulturchem. Inst., Justus Liebig Hochsch., Giessen.]

Alfalfa was ensiled in 300 kg. portions, either fresh or after wilting for 24 or 32 hr. In all cases Kofasalt was added as preservative. The silos were opened after 8 months and the contents were weighed and analysed. In general, wilting did not affect the slight losses in the silo and had no marked effect on the quality of the silage, except to raise the pH and increase the percentage of total volatile acids. Butyric acid was absent from all samples and the increase was entirely in lactic acid.—W. Godden.

KIERMEIER, F. and CODURO, E. **Über das Vorkommen von Enzymen in Brot.** [Occurrence of enzymes in bread.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **96**, 405-409. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

Estimations of enzyme activity in different types of bread showed that in some cases amylolytic and proteolytic enzymes could survive the baking process. "Knäckebröt" showed specially high amylolytic activity, and the presence of proteases was demonstrated also. In "Vollkornschrotbröt" (rye wholemeal bread) and "Schlüterbröt" (a wholemeal fine bread) the amylolytic activity was

considerably less than in "Knäckebröt" but still distinctly positive; protease activity was not demonstrable. In breads kept moist for some time during the baking process, e.g., "Pumpernickel" and "Simonsbröt", the enzymes were completely inactivated.—M. B. Richards.

289

WOOD, E. C. **The efficient planning of microbiological assays.** *Analyst*, 1953, **78**, 451-460 (with discussion 460). [Clarence House, Clarence Rd., Norwich.]

The design of many assays of vitamins and amino-acids for which the relation between response and dose is curvilinear is described and criticised.

Vol. 24, No. 1

With assays of cobalamin as illustration, it is argued that only a limited section of the response curve is of use and doses outside this range contribute nothing to the determination. It would be wiser to increase the number of doses to ensure that an adequate number do fall in the useful range.

After this general criticism, the lack of precision in such an assay and the general lack of amenability of the result to objective assessment are discussed. The curve for log-response and log-dose is then shown to be linear over a considerable range of dose and to such a relationship statistical analysis is readily applicable.

Efficient designs to use this relationship are then discussed and in a statistical appendix a number of designs are given together with the form of analysis applicable to each.—G. T. Park.

290

SCHOEN, G. **Analisi cromatografica su carta delle vitamine.** [Chromatographic analysis of vitamins on paper.] *Acta vitaminol.*, 1953, **7**, 151-167. [Lab. Ric., Lepetit S.p.A., Milan.] French, English, German and Spanish summaries.

Some account is given of the behaviour in paper chromatography of vitamins A and D, vitamin B₁,

thiochrome, riboflavin, vitamins B₆ and B₁₂, folic acid, nicotinic acid, nicotinamide and pantothenic acid, and their derivatives, also of the tocopherols, ascorbic and dehydroascorbic acid, and vitamin P and substances akin to it. Tables are given in which is collected information about suitable solvents, type of paper, *R_F* value, and method of identifying the spots, with the references, for the various substances. There are also diagrams showing the position of the spots with different solvents.—E. M. Hume.

291

LEE, Y. C. P., KING, J. T. and VISSCHER, M. B. **Strain difference in vitamin E and B₁₂ and certain mineral trace-element requirements for reproduction in A and Z mice.** *Amer. J. Physiol.*, 1953, **173**, 456-458. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

Female mice of the A and Z strains were given at weaning a basal diet of casein, glucose, lard, brewer's yeast, alfalfa meal, cod liver oil, wheat germ oil and salt mixture. Reproductive capacity was measured as the number of young born alive and the number alive at weaning. With the basal diet alone the average number born alive to the A strain mice was 4.7 and the average number alive at weaning was 4.7, and for the Z strain mice the corresponding values were 0.2 and 0. For the Z strain mice the addition of 8 per cent. wheat germ oil to the diet increased the averages to 3.7 and 0.9, respectively. α -Tocopherol in amounts of 8, 16 and 32 mg. per cent. gave averages of 4.3 and 2.8, 5.3 and 2.0, and 5.6 and 2.5. Addition of yeast and alfalfa had no effect. Vitamin B₁₂ as 6 μ g. per cent. gave average values of 6.6 and 1.6 and an animal-protein factor added as 1.5 per cent. gave average values of 4.3 and 0. A change in the composition of the salt mixture also increased both averages.

R. J. Ward.

292

INGLE, D. J., NEZAMIS, J. E. and MORLEY, E. H. **Failure of certain vitamins to affect the survival of the eviscerate rat.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 602-603. [Res. Labs., Upjohn Co., Kalamazoo, Mich.]

Adult male rats were eviscerated by the method described by Ingle (*Exp. Med. Surg.*, 1949, **7**, 34) and received intravenously 0.9 per cent. NaCl, glucose, insulin, streptomycin and penicillin, with or without a mixture of vitamins B₁, B₆, B₁₂, A, D and E, folic acid, riboflavin, pantothenate and nicotinamide. There were no differences in survival times between the groups. Preliminary tests with the mitochondria fraction of rat liver extracts to provide co-enzymes of the vitamins and with several extracts of beef liver were negative also.—V. R. Jackson.

293

DE BARBIERI, A. and GERRA, A. **Eliminazione per via renale di vitamine nell'ipercorticalismo da ACTH. [Excretion of vitamins through the kidneys in a state of cortical excess caused by adrenocorticotrophic hormone.]** 1. Ricerche sulla tiamina, la riboflavina, la niacina e l'acido pantotenico. [1. Vitamin B₁, riboflavin, nicotinic acid and pantothenic acid.] 2. Ricerche sulla piridossina, la cianocobalamina e l'acido ascorbico. [2. Pyridoxine, cyanocobalamin and ascorbic acid.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 127-129; 129-131. [Lab. Biochim., Ist. Sieroterap., Milan.]

1. Urine was collected from rats of about 120 g. weight, fed on a complete diet. For a preliminary period of 15 days the animals were given a daily injection of saline, after which 0.5 unit adrenocorticotrophic hormone was injected twice daily for 10 days. Ascorbic acid and the B vitamins were estimated in the urine. The daily amounts excreted, in μ g., before and during administration of the hormone, respectively, were riboflavin 108.6 and 93.4, nicotinic acid 239.3 and 130.8, and pantothenic acid 725.5 and 861.9.

2. In the same way values were obtained for vitamin B₆ 127.6 and 97.3 μ g., ascorbic acid 1450 and 983 μ g. and vitamin B₁₂ 493.5 and 182.1 μ g. Except for pantothenic acid, the excretion of all the vitamins estimated was decreased by hormone administration.—E. M. Hume.

294

BOSCOTT, R. J. and GREENBERG, S. M. **The effect of dietary deficiencies, aminopterin, ascorbic acid, chloretone, and antibiotics, on the urinary excretion of phenolic acids in the rat.** *Biochem. J.*, 1953, **55**, xviii. [Dept. Anat., Univ. Birmingham.]

295

USUELLI, F. and PIANA, G. **Fattori alimentari e genetici nella profilassi delle malattie infettive.** 4.5. [Dietary and genetic factors in the prevention of infective diseases. 4.5.] *Riv. Zootec.*, 1953, **26**, 165-168; 202-207.

For previous sections, see Abst. 5352, Vol. 23.

4. The possible effect is reviewed of vitamin E and of vitamin K on resistance to *Brucella* infection in farm animals. Certain work on guinea pigs with *Brucella abortus* by the authors' colleague, Dr. Curto [apparently unpublished, since no reference is given] is quoted. His results are considered to show that treatment with vitamin E favourably influences the degree of resistance to the infection but does not offer an effective means of prophylaxis.—E. M. Hume.

5. Deficiency of the vitamin B complex is discussed in relation to resistance to infection.

N.A. and R., January 1954

The importance of the vitamin B complex in protein metabolism and in the formation of antibodies is considered.—T. D. Bell.

296

VELTRE, F. A., SHORB, M. S. and PELCZAR, M. J. (Jr.) **Nutritional requirements of *Lactobacillus bifidus* isolated from poults and chicks.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 284–286. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Strains of *Lactobacillus bifidus* from the caecum of turkeys and chickens were maintained with monthly transfer on a medium containing papaic digest of soya bean. None would grow in the purified medium containing 25 mg. Na acetate per ml. which supported *L. bifidus* of human origin. When the medium was diluted, growth occurred

only in the presence of the soya bean digest or other crude substance such as yeast extract, beef extract or fish solubles. Several vitamins and other compounds were tested, but the requirements of the avian strains appeared to differ from those of the human strain. The avian strains did not lose their branched structure after from 1 to 2 years in culture, nor did they become aerobic, but they could be grown aerobically in presence of ascorbic acid.—V. R. Jackson.

LITSKY, W., ESSELEN, W. B. (Jr.), TEPPER, B. S. and MILLER, G. **Nutritive requirements of *Acetobacter*. 1. Vitamin requirements of *Acetobacter xylinum*.** *Food Res.*, 1953, **18**, 250–252. [Massachusetts Agric. Exp. Stat., Amherst.]

VITAMIN A

298

MURRAY, T. K. and CAMPBELL, J. A. **A comparison of physical and chemical methods with biological assay of vitamin A.** *J. Pharm.*, 1953, **5**, 596–607. [Food and Drug Labs., Dept. Nat. Health, Ottawa.]

The procedure of Morton and Stubbs applied to the estimation of vitamin A gave a more accurate assessment of the biological potency of market samples of fish liver oils than that given by the SbCl_3 method or by uncorrected spectrophotometric measurements. It gave also the best estimate of the biological potency of a partially oxidised cod liver oil. Application of the correction distinguished between halibut liver oils and concentrates on the one hand and cod liver oils on the other. With the former the correction gave similar results for oils and for the unsaponifiable fraction, with the latter it gave higher results for the oils. The practice of multiplying uncorrected E values by 1600 did not indicate accurately the vitamin A content of cod liver oils or concentrates, giving usually too high a value, but appeared to be satisfactory for halibut liver oils. The potency of neovitamin A was found to be 72 per cent. of that of all-*trans* vitamin A when estimated biologically by the vaginal-smear method.

MOOR, H. **Die Bestimmung von Vitamin A in Lebens- und Futtermitteln.** (Auswertung nach Carr-Price.) **[Estimation of vitamin A in foods and feedingstuffs. (Carr Price method.)]** *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 257–264. [Hoffmann-La Roche Co., Basle.] French and English summaries.

Vol. 24, No. 1

The material under examination was homogenised and extracted with ether. Arachis oil was added if the yield of fat was only small, and saponification was effected with alcoholic NaOH in presence of hydroquinone. The soaps were concentrated by partial evaporation of the solvent and then mixed with alumina. The vitamin fraction was extracted with ether, and the SbCl_3 reagent was applied, with or without further purification by chromatography on alumina weakened with 12 per cent. of water, according to the material. The loss of added vitamin A submitted to the processes for saponification and chromatography never exceeded 7 per cent. An accuracy of ± 3 to 6 per cent. is claimed. For milk, ammonia was used for the preliminary extraction, according to the Röse Gottlieb method.

AVAMPATO, J. E. and EATON, H. D. **Comparison of methods for the estimation of vitamin A in**

calf plasma. *J. Dairy Sci.*, 1953, **36**, 783-793. [Dept. Animal Indust., Univ. Connecticut, Storrs.]

Specimens of calf plasma containing low and high amounts of carotenoids were extracted by a modification of Kimble's method and subjected to 4 different treatments: saponification without separation of carotene and vitamin A; saponification followed by separation of carotene by precipitation and by chromatography on alumina; the same two treatments without saponification. Vitamin A was estimated by the SbCl_3 reaction in an Evelyn photo-electric colorimeter, by the glycerol dichlorohydrin method and a Coleman Model 14 spectrophotometer, and by ultraviolet absorption at 325 $\mu\mu$. with the Beckman Model D.U. spectrophotometer. Carotenoids were estimated at 440 $\mu\mu$. with each of the instruments. Values for carotene obtained with the Evelyn colorimeter were less than with the other instruments. Saponification without separation had little effect on the carotene values, but the values obtained by both methods of separation without saponification were lower, and were still lower when the plasma was saponified as well.

Both colorimetric methods for vitamin A gave lower total values than ultraviolet absorption. The SbCl_3 method gave higher values than the glycerol dichlorohydrin method for the plasma with a high carotene content. Separation had little effect on the total vitamin A content, but separation of carotene was more efficient for non-saponified samples by the precipitation method and for saponified samples by the chromatography method.—R. J. Ward.

CALLISON, E. C., HALLMAN, L. F., MARTIN, W. F. and ORENT-KEILES, E. (with CONWAY, E. S. and CRUMP, E.) **Comparison of chemical analysis and bio-assay as measures of vitamin A value: yellow corn meal.** *J. Nutrition*, 1953, **50**, 85-100. [Bur. Human Nutrit., Agric. Res. Admin., U.S. Dept. Agric., Washington, D.C.]

The carotenoid pigments from a specimen of yellow maize meal were extracted, separated chromatographically and studied spectrophotometrically. The vitamin-A-active carotenoids present included, in μg . per 100 g. meal, cryptoxanthin 236.6, all-*trans*- β -carotene 31.1, *neo*- β -carotene B 39.6 and *neo*- β -carotene U 21.5. A considerable quantity of another pigment, probably ζ -carotene, was present which, with lutein, zeaxanthin and other pigments of no vitamin A value, was excluded from the calculations. The sum of the biological potencies of the 4 active carotenoids was calculated to be 317 I.U. per 100 g. An extract was prepared from the same meal with fat solvents

and saponified; the unsaponifiable portion was dissolved in cottonseed oil, and the potency of the oily solution was estimated by rat growth against β -carotene. In terms of the original meal the activity was 324 I.U. per 100 g., which confirms the value of 317 obtained by calculation. The biological potency of the whole meal for rats was 264 I.U. per 100 g. The availability of the carotenoids in the whole meal was, therefore, 82 per cent. It is suggested that the lower availability reported by others may be due to the inclusion in the chemical estimation of biologically inactive pigments.

STROSS, P. and STUCKEY, R. E. **An adsorption method for the measurement of vitamin A stability.** *J. Pharm.*, 1953, **5**, 547-549. [British Drug Houses, Ltd., London.]

The stability of oils containing vitamin A when present in tablets or when adsorbed on solids was estimated at temperatures of 25° and 37° C. in preference to the higher temperatures usually employed, which are liable to cause thermal decomposition. Ca phosphate, Kieselguhr, Ba sulphate and silica were tried as adsorbents. Ca phosphate B.P. was the most suitable, as it gave even distribution of the oil, moderate speed of decomposition and ease of extraction.

FISHER, L. R., KON, S. K. and THOMPSON, S. Y.
Vitamin A and carotenoids in certain invertebrates. 1. Marine crustacea. *J. Marine Biol. Assoc.*, 1952, **31**, 229-258. [Nat. Inst. Res. Dairying, Shinfield, Reading.]

Specimens of plankton were collected in Loch Fyne, the Faeroe and Shetland area, and off the coast of Norway. Krill (euphausiids) was obtained from whales in arctic and antarctic waters, and littoral and benthic animals were collected from Loch Fyne and the Essex coast. Samples were analysed for vitamin A, total carotenoids and β -carotene. Extracts were saponified directly and then subjected to chromatography on aluminium oxide or were submitted to direct chromatography, to separate vitamin A ester and alcohol. Vitamin A was estimated by chemical, physical and biological tests, and carotenoids by their natural colour. Free-swimming arctic krill contained from 288 to 835 I.U. vitamin A per g. oil. No carotene was present but there were large amounts of astaxanthin. In krill recovered from the stomachs of arctic whales smaller concentrations of vitamin A were found, ranging from 188 to 392 I.U. per g. oil. In *Meganyctiphanes norvegica* the vitamin A content increased with the size of the animal from 455 I.U. per g. oil when 17 mm. long to 1120 I.U. when 39 mm. long. No such change was found in specimens of *Thysanoessa raschii*. In both species, however, the content of astaxanthin rose with the size of the animal. Of the total vitamin A in the euphausiids examined, 92 to 98 per cent. was in the eyes, and the remainder was in the exoskeleton and contents of the cephalothorax. Most of the astaxanthin also was present in the eyes. The function of astaxanthin in the *Crustacea* is discussed. Vitamin A concentration was much less in decapods because less was present in the eyes. No vitamin A was found in the amphipods, isopods and cladocera examined. Biological tests of the oils on rats showed only about half the activity indicated by chemical and physical tests. The high content of vitamin A in euphausiids which supply the main food of whales is sufficient to account for the rich stores found in whale liver.—I. M. Sharman.

PINCKARD, J. H., KITTREDGE, J. S., FOX, D. L., HAXO, F. T. and ZECHMEISTER, L. **Pigments from a marine "red water" population of the dinoflagellate *Prorocentrum micans*.** *Arch. Biochem. Biophys.*, 1953, **44**, 189-199. [Gates and Crellin Labs., California Inst. Technol., Pasadena.]

During an occurrence of red water in the sea off the Pacific coast, samples consisting almost entirely of the brownish dinoflagellate, *Prorocen-*

trum micans, were taken and analysed. The main carotenoid was peridinin, but small amounts of epiphasic carotenoids, chiefly β -carotene, were present.—E. M. Hume.

310

RUSHTON, W. A. H. **The measurement of rhodopsin in the living eye.** *Acta physiol. scand.*, 1953, **29**, 16-18. [Cambridge.]

Rhodopsin was estimated in the eye of the living albino rabbit with the rhodopsinometer previously described by the author (*J. Physiol.*, 1952, **117**, 47). The eye was light-adapted, and measurements were made over an hour with green light focused on the retina and the reflected light received on a photocell.

The optical density of the retina measured in red light did not change with accumulation of rhodopsin, and remained fairly constant. The density in violet light also was nearly constant, being independent of rhodopsin but dependent on the blood content of the retina. The density in blue-green light, which estimated the amount of rhodopsin, increased at a constant rate. Strong light, 10^6 times the human threshold, bleached the rhodopsin quickly. The total density which accumulated was attained and maintained at an illumination 10^5 times the human threshold, and represented absorption of 35 per cent. of the incident light on a single passage through the retina.

POWELL, L. T. and KRAUSE, R. F. **Vitamin A distribution in the rat liver cell.** *Arch. Biochem. Biophys.*, 1953, **44**, 102-106. [Dept. Biochem., Sch. Med., W. Virginia Univ., Morgantown.]

Rats were given a normal diet for 2 weeks with and without a daily supplement of from 6200 to 7500 I.U. vitamin A given orally for the second week. At the end of the 2 weeks the animals were killed and their livers were removed, weighed, chilled in cold 0.25 M sucrose and frozen at -20°C . When required, the livers were thawed and forced through a tissue mincer which allowed only free cells to pass. A weighed quantity was homogenised in 0.25 M sucrose, diluted to 15 ml., and 10 ml. were taken for preparation of the cytoplasmic fractions, which were designated nuclei, mitochondria and fraction X. Total N and vitamin A content were estimated in each fraction. Vitamin A was present in all fractions from normal and supplemented animals. The concentration was highest in fraction X in both, lowest in the nuclei from normal animals and in the mitochondria from supplemented animals. In the nuclear fraction, on supplementation, the average content of vitamin A increased 345 per cent. above

the average normal, while with mitochondria and fraction X the increase was 230 and 141 per cent., respectively.—R. J. Ward.

312

KRAUSE, R. F. and POWELL, L. T. **The *in vitro* hydrolysis and esterification of vitamin A.** *Arch. Biochem. Biophys.*, 1953, **44**, 57–62. [Dept. Biochem., Sch. Med., W. Virginia Univ., Morgantown.]

Rat liver homogenates were separated into mitochondria, nuclei and fraction X and each fraction was suspended in 0.25 *M* sucrose. Intestine and kidney homogenates also were suspended in 0.25 *M* sucrose. Each suspension contained 200 mg. tissue per ml. Aqueous dispersions of natural vitamin A esters, vitamin A palmitate, acetate and alcohol were incubated with an equal quantity of suspension and 10 times the amount of veronal buffer for 3 hours at 37° C. The amount of the vitamin in alcohol and ester form was estimated before and after incubation. The only increase in the content of the alcohol occurred with the acetate; a percentage increase of 506 was obtained with a whole liver homogenate, of 670 with nuclei, of 428 with mitochondria, and of 509 with fraction X; the respective percentage decreases in the amount of ester were 37.6, 43.8, 37.8 and 21.8. When the palmitate was incubated with fraction X, no decrease in ester occurred, but there was a percentage decrease of 12.1 with whole liver homogenate, of 15.7 with nuclei and of 37.8 with mitochondria. With the two specimens of natural esters the percentage decrease in ester in the 4 suspensions ranged from 2.7 to 11.8.

On incubation of vitamin A alcohol with liver homogenates no increase in ester form occurred, but with intestine and kidney homogenates the increase was 186 and 100 per cent.—R. J. Ward.

313

GANGULY, J. and DEUEL, H. J. (Jr.) **Intracellular distribution of vitamin A esterase activity in rat liver.** *Nature*, 1953, **172**, 120–121. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

Male rats, reared on a diet without vitamin A and given 15 to 20 I.U. vitamin A weekly, were killed by heart puncture under light nembutal anaesthesia. The liver, freed from residual blood, was homogenised in 0.25 *M* sucrose solution and the homogenate was fractionated by differential centrifuging. All fractions were diluted so that each contained 200 mg. of original tissue per ml. Crystalline vitamin A acetate was freed from vitamin A alcohol by chromatography, and dispersed in water. It was incubated with the fractions and extracted by the method of McGugan and Laughland (Abst. 1798, Vol. 22); the free

alcohol and ester were estimated by the method of Ganguly *et al.* (Abst. 256, Vol. 23). Preliminary experiments indicated that the esterase activity was concentrated in the microsomal fraction only, the chondrial and supernatant fractions being inactive.—R. J. Ward.

314

ROSENBERG, A. and SOBEL, A. E. ***In vitro* conversion of carotene to vitamin A in the isolated small intestine of the rat.** *Arch. Biochem. Biophys.*, 1953, **44**, 320–325. [Dept. Biochem., Jewish Hosp., Brooklyn, N.Y.]

An aqueous dispersion of carotene containing α -tocopherol was prepared and 0.5 ml. portions, providing 150 μ g. carotene, were introduced by tube into the stomachs of rats deficient in vitamin A. The animals were killed immediately and the contents of the stomach were squeezed into the small intestine which was tied with surgical silk thread and incubated for 2 hr. in Ringer solution at 45° C. The intestinal contents were then flushed out and the gut tissue was examined for vitamin A by measurement of the spectral absorption of the non-saponifiable lipid at 328 $m\mu$. before and after destructive irradiation. It is claimed that the method accurately estimated vitamin A because the curve resulting from the difference in the absorption spectrum between 310 and 390 $m\mu$. before and after irradiation closely resembled the absorption curve of pure vitamin A. In the walls of the small intestine of 10 animals an average of 4.24 μ g. vitamin A was found with a standard deviation of ± 1.53 and a standard error of the mean of 0.39. It is concluded that the small intestine is an important site of conversion of carotene to vitamin A in the rat.—I. M. Sharman.

315

ROSENBERG, A. and SOBEL, A. E. ***In vitro* conversion of carotene to vitamin A in alloxan diabetes.** *Arch. Biochem. Biophys.*, 1953, **44**, 326–329. [Dept. Biochem., Jewish Hosp., Brooklyn, N.Y.]

Rats deficient in vitamin A were divided equally into 2 groups. Diabetes was produced in one group by subcutaneous injection of alloxan, and the other was untreated. An aqueous dispersion of carotene and tocopherol was administered to each animal. The intestine was removed and after incubation carotene and vitamin A were estimated in the intestinal walls. The mean amount of vitamin A produced in the intestinal loops of 10 non-diabetic animals was 4.24 μ g. with a standard deviation of ± 1.53 ; the mean for 10 diabetic animals was only 0.76 μ g., S.D. ± 0.50 . It is concluded that in alloxan-diabetic rats the mechanism by which carotene is converted into

vitamin A is impaired, and that the small storage of vitamin A in the livers of such rats when given carotene is probably due to the impairment.

I. M. Sharman.

316

SOBEL, A. E., ROSENBERG, A. and ADELSON, H. **In vivo conversion of carotene to vitamin A in alloxan diabetes.** *Arch. Biochem. Biophys.*, 1953, **44**, 176-180. [Dept. Biochem., Jewish Hosp., Brooklyn, N.Y.]

Albino rats were fed on a diet deficient in vitamin A until they became depleted. Most of them were then injected subcutaneously with 20 mg. alloxan monohydrate, and the remainder were kept untreated. All were given 2000 μ g. carotene 24 hr. later and, after a further 36 hr., were killed and their blood and livers were analysed for vitamin A. The nondiabetic rats stored an average of 88 μ g. vitamin A in their livers, the diabetic animals only 22 μ g. The difference was shown not to be caused by loss of storage ability or by abdominal destruction of vitamin A because, when similar rats were given 1000 μ g. preformed vitamin A, the diabetic animals stored 90 μ g. in the liver and the nondiabetic ones 123 μ g., a difference which was not statistically significant. The results are considered to indicate an impairment in the alloxan-diabetic rat of the system responsible for the conversion of carotene to vitamin A.

I. M. Sharman.

317

HEBERT, J. W. and MORGAN, A. F. **The influence of alpha-tocopherol upon the utilization of carotene and vitamin A.** *J. Nutrition*, 1953, **50**, 175-190. [Dept. Home Econ., Univ. California, Berkeley.]

Weanling male rats, usually in groups of 10, were fed on a diet lacking vitamins A and E. After 2 weeks, when they were partially depleted of the vitamins, the animals were given daily for 14 days, a few for 28 days, carotene in oil, 24 to 174 μ g., or vitamin A in oil, 35 to 129 μ g., with or without a daily supplement of 0.5 mg. α -tocopherol. After the prescribed interval of treatment the animals were killed 3 hr. after the last dose, and the vitamin A content of the serum, liver and intestinal tissues was estimated. In none of the experiments with the above doses of carotene in oil was any vitamin A found in the intestinal walls.

When vitamin A was given no difference in growth or in serum or liver content of vitamin A could be ascribed to the supplement of tocopherol, except with the lowest dose of vitamin A, 35 μ g., when, after 28 days, an average of 64 μ g. vitamin A was found in the liver of those animals given tocopherol and only 27 μ g. in those not given tocopherol. When carotene was given in the higher doses, somewhat greater stores of vitamin A were

found in the livers of those animals which received tocopherol also. The groups given carotene for 4 weeks instead of 2 showed the effect more clearly, possibly because the growth rate and utilisation of vitamin A had been slightly reduced in the later part of the period. In a further experiment the dose of tocopherol was 1.0 mg. as well as 0.5; the animals were killed 24 hr. after the last dose and the kidneys, in addition to the liver, were analysed for vitamin A. No significant difference was found between the amount of vitamin A in the liver and kidneys of the groups without tocopherol or given 0.5 or 1.0 mg. tocopherol when 43 or 86 μ g. carotene were given daily for 14 days. When aqueous dispersions with Tween 80 of carotene were given to rats the store of vitamin A in the liver was reduced by giving 0.5 mg. tocopherol orally or intraperitoneally. In still further experiments, single doses of 390 μ g. aqueous carotene were given to depleted animals and it was found that vitamin A appeared in the intestinal wall after 30 min., that the amount increased up to one hour and was maintained up to 2½ hr. but had all disappeared after 3 hr. Vitamin A appeared in the liver after 1½ hr. and increased in amount up to the end of the experiment after 3 hr.

I. M. Sharman.

318

HIGH, E. G. and WILSON, S. S. **Effects of vitamin B₁₂ on the utilization of carotene and vitamin A by the rat.** *J. Nutrition*, 1953, **50**, 203-212. [Lab. Biochem. Res., Prairie View Agric. and Mech. Coll., Tex.]

Young rats were depleted of vitamins A and B₁₂ and then given daily supplements of 38 μ g. carotene in cottonseed oil for 21 days. In addition, every other day, one group received an intramuscular injection of 0.2 ml. saline, and the other group received 0.2 ml. saline containing 0.28 μ g. vitamin B₁₂ as Cobione, Normocytin or liver extract. The rats which received vitamin B₁₂ grew about 50 per cent. more than those which did not, and the deposition in the liver of vitamin A from the carotene given was 37 per cent. greater. When sulphasuxidine was added to the diet during the depletion period to inhibit microbial synthesis of vitamin B₁₂, the average superiority in growth of those given vitamin B₁₂ was 62 per cent., and liver deposition rose from 36.6 μ g. to 57.0 μ g. Addition of an animal-protein factor supplement to supply 55 μ g. vitamin B₁₂ per kg. diet resulted in a 12 per cent. superiority in weight over a group not given vitamin B₁₂, and storage of vitamin A in the liver increased from 39.7 to 49.9 μ g. When 33 μ g. vitamin A was administered in the same way, instead of 38 μ g. carotene, growth was increased but liver deposition was hardly affected.—R. J. Ward.

319

HARTSOOK, E. W., BATCHELOR, E. and JOHNSON, B.C.

Effect of aureomycin on utilization of vitamin A in the growing male albino rat. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 43-45. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Groups of male rats were given a diet deficient in vitamin A alone, or with 0.75 or 7.5 μ g. vitamin A daily with or without 100 mg. aureomycin, per kg. diet. The average weight gains of the 3 groups without aureomycin were 75.6, 198.5 and 251.6 g. and with aureomycin 66.9, 180.2 and 252.9 g., respectively. The typical syndrome of vitamin A deficiency developed in the groups receiving no vitamin A, and the signs appeared earlier in those receiving aureomycin. Storage of vitamin A occurred only in the rats receiving 7.5 μ g. daily of vitamin A. The average vitamin A content of the kidneys and livers of rats receiving vitamin A without aureomycin was 3.7 μ g. total and 2.2 μ g. per g., and 75.9 μ g. total and 7.8 μ g. per g., respectively, compared with 1.5 μ g. total and 0.9 μ g. per g., and 79.6 μ g. total and 6.5 μ g. per g. for those receiving both vitamin A and aureomycin.—R. J. Ward.

ASCHAFFENBURG, R., BARTLETT, S., KON, S. K., ROY, J. H. B., SEARS, H. J., THOMPSON, S. Y., INGRAM, P. L., LOVELL, R. and WOOD, P. C. **The nutritive value of colostrum for the calf. 9. The effect of soya-bean lecithin on the vitamin A absorption and on the growth rate of calves given small quantities of separated colostrum.** *Brit. J. Nutrition*, 1953, **7**, 275-285. [Nat. Inst. Res. Dairying, Univ. Reading.]

In two experiments, one in autumn and one in spring, calves were reared on a basal synthetic milk diet with and without colostrum, lecithin and vitamin A. All the calves receiving the basal ration alone died in from 3 to 5 days. Of the 62 calves given colostrum, 8 died in from 5 to 13 days. Administration of vitamin A with or without lecithin had no effect on scouring or on the growth rate. Lecithin supplementation had no effect on the plasma levels of vitamin A. In the first of the two experiments, but not in the second, lecithin significantly increased the vitamin A content of the liver of calves which received 80,000 I.U. vitamin A from about 8000 to about 15,000 I.U.—R. J. Ward.

321

LE GALLIC, P. **Structure des protéines et activité vitaminique A manifestée par les protéines en présence de saindoux ou de distillat de saindoux.** [Structure of proteins and vitamin A

activity of proteins in the presence of lard or lard distillate.] *C.R. Soc. Biol.*, 1953, **147**, 302-306. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

Young rats were depleted of vitamin A with a diet of casein, wheat starch, dried yeast, vitamin D₂ and minerals. The casein was purified by extraction with aqueous acetone, followed by pure acetone and by ether. Groups were then given diets containing the same casein or peptone made from it, with 21.5 per cent. of lard or 6 or 12 per cent. of lard distillate to replace some of the starch. The animals kept on the original diet, or given lard or lard distillate with peptone, died in from 4 to 10 days. The animals given the lard or distillate with casein survived for from 20 to 50 days. No vitamin A was detected in the lard or distillate by the SbCl₃ test. A combination of casein and lard distillate prolonged growth even when the casein had been purified by anionic detergents. The vitamin A activity of lard distillate was, thus, shown only in the presence of casein. The phenomenon appeared to depend on the establishment of a nutritive equilibrium, as first postulated by Randoin and Netter (*Abst.* 1105, Vol. 4).—T. Moore.

HALL, W. T. K. and HARVEY, J. M. **Effects of methyl-thiouracil on liver vitamin A, spermatogenesis and calcium metabolism of Merino rams.** *Queensland J. Agric. Sci.*, 1952, **9**, 301-316. [Animal Health Stat., Yeerongpilly.]

Groups of 6 Merino rams aged from 18 to 24 months were fed on a basal ration low in carotene, made up of oat chaff and linseed meal. One group received the basal ration only, another was given additional carotene and 2 further groups received daily 2 g. 4-methylthiouracil, one with and one without carotene. After 100 days the animals were killed and the weight of the thyroid gland and testes, serum Ca and liver vitamin A were measured. The mean weight of the thyroids, 16.5 g., of the animals receiving thiouracil was over four times that of the thyroids from the animals without. Serum Ca of those not receiving thiouracil was somewhat less, range 4.0 to 10.6 mg. per 100 ml., than of those in the other groups, range 7.2 to 11.0 mg. per 100 ml. Liver vitamin A varied from 55 to 190 μ g. per g. within the groups, but no difference was found between groups, which suggested that the hypothyroid state, shown by enlarged thyroids and lethargy, had not

N.A. and R., January 1954

prevented conversion of carotene to vitamin A. The extent of the hypothyroidism was, moreover, more severe than that likely to be brought about in the field by starvation or climatic conditions. Semen, collected at 3-week intervals during the feeding period, showed no difference between the groups.—I. M. Sharman.

HELMBOLDT, C. F., JUNGHERR, E. L., EATON, H. D. and MOORE, L. A. **The pathology of experimental hypovitaminosis A in young dairy animals.** *Amer. J. Vet. Res.*, 1953, **14**, 343-354. [Dept. Animal Dis., Storrs Agric. Exp. Stat., Univ. Connecticut.]

Calves were reared on a diet of whole milk, dried calf starter and hay until they were 63 or 105 days old. They were then restricted to a diet deficient in vitamin A, mainly of grain mixture and sugar beet pulp. Some of the calves were given supplements of about 100,000 I.U. vitamin A daily. Others were kept on the deficient diet until the value for vitamin A in the blood plasma had fallen to 4 μ g. per 100 ml. or less. Some were killed without treatment 2 or 7 weeks later, at ages of from 105 to 177 days. Others were given daily for 6 days, subcutaneously or orally, an aqueous dispersion of β -carotene at the rate of 120 μ g. per lb. bodyweight, and were killed 14 days later. Further groups were killed after 14 days' treatment with 200,000 I.U. vitamin A daily, or 14 days after they had been given daily injections of 2 g. ascorbic acid for 6 days. In calves untreated, or in which treatment was insufficient, diarrhoea and inco-ordination were consistently found. The spinal fluid pressure was increased. Histological examination revealed squamous metaplasia of the interlobular and main ducts of the parotid gland in all but one animal; the lesion may be considered pathognomonic. Focal necrotic hepatitis was less frequent, but occurred only in deficient animals. A cystic pituitary gland was found in one of the deficient calves and in none of the controls. In the animals treated for 2 weeks with vitamin A the epithelium of the parotid glands was partially restored, and after 4 weeks the cure was complete. Spinal fluid pressure was reduced, and the signs of vitamin A deficiency disappeared. Carotene cured the diarrhoea and inco-ordination, but did not reverse the changes in the parotid glands. Ascorbic acid had no curative effect.—T. Moore.

BAUME, L. J. and FRANDSEN, A. M. **Phase contrast microscope study of oral epithelium of normal and vitamin A-deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 356-360. [George Williams Hooper Found., Coll. Dent., Univ. California.]

Specimens, described as "briefly formalin-fixed", of the gingival papilla situated between the upper incisors from normal rats and from rats deficient in vitamin A were frozen, sectioned and examined in a suspension of saline. Photomicrographs were taken by the phase contrast technique immediately after sectioning. Sections from 4 rats which had survived for 86 days on a diet deficient in vitamin A differed from the normal in showing aplasia of the basement membrane, causing lack of a distinct border between epithelium and connective tissue, precocious granular involution of the tonofibrils in the stratum spinosum, and parakeratosis of the surface layer.—I. M. Sharman.

PICCIONI, M. **Sulla azione protettiva della vitamina E nella avitaminosi sperimentale A del ratto. [Protective action of vitamin E in experimental vitamin A deficiency in the rat.]** *Quad. Nutrizione*, 1952, **12**, 403-413. [Ist. Chim. Biol., Univ. Bologna.]

When rats were deprived of vitamin A from 15 days old and were weaned at 25 days, 90 per cent. of them showed signs of vitamin A deficiency within another 20 to 25 days. With their offspring reared in the same way, vitamin E was administered orally to the mother from mating to weaning of the young but not directly to the young, or

orally directly to the young from the 15th to the 30th day of age, without effect on the course of depletion. In curative tests with 1.5 I.U. vitamin A daily, recovery from signs of deficiency and rate of growth were more rapid when vitamin E was given as well. It is concluded that such an effect of vitamin E *in vivo* was of the same nature as the protective effect exercised by it over vitamin A *in vitro*.—E. M. Hume.

ERSHOFF, B. H. and GREENBERG, S. M. **Effects of a transient vitamin A deficiency on survival following X-irradiation.** *Exp. Med. Surg.*, 1953, **11**, 46-48. [Emory W. Thurston Labs., Los Angeles.]

Young rats reared to have low reserves of vitamin A were maintained from weaning on a vitamin-A-free diet. Half of them received 50 U.S.P.U. vitamin A 6 times weekly from weaning but half of them did not receive the supplement until 3 weeks after weaning. After 14 weeks the groups were outwardly indistinguishable, and 16 from each group received a single exposure to X-rays of 750 r. In the ensuing 50 days almost all the rats in both groups died, but the survival time of those that had suffered depletion was 12.7 ± 1.7 days, and of those that had not 26.2 ± 3.0 .—E. M. Hume.

GANGULY, J., MEHL, J. W. and DEUEL, H. J. (Jr.) **Studies on carotenoid metabolism. 12. The effect of dietary carotenoids on the carotenoid distribution in the tissues of chickens. 13. The carotenoid composition of the blood, liver and ovaries of the rat, ewe, cow and frog.** *J. Nutrition*, 1953, **50**, 59-72; 73-83. [Dept. Biochem., Univ. S. California, Los Angeles.]

12. The blood plasma of laying hens, reared on a general farm diet, contained, per 100 ml., 162 μ g. lutein but only 4.2 μ g. β -carotene. Considerable amounts of lutein and only small quantities

of β -carotene were found also in the ovaries and body fat of the hens and in the yolks of their eggs. Day-old chicks fed on a diet deficient in carotenoids yielded hens whose tissues were devoid of carotenoids. Chickens devoid of carotenoids when given 7 mg. cryptoxanthin every 3 days contained 213 μ g. cryptoxanthin per 100 ml. plasma and 5.4 μ g. per g. liver. Carotenoid-free hens when given 7 mg. zeaxanthin every 3 days had 526 μ g. zeaxanthin per 100 ml. blood plasma, 3.4 μ g. per g. liver and 68.6 μ g. per g. ovary. When α - or β -carotene was given only traces were found in the blood, and small quantities only in the liver, ovaries and egg yolks. When 24 mg. lycopene were given in 12 days the values for it were 7.2 μ g. per 100 ml. plasma, 1.4 μ g. per g. liver and 1.2 μ g. per g. ovary. When doses ranging from 2 to 6 mg. of α - or β -carotenes or zeaxanthin in colloidal solution were injected intravenously no carotenoid was found in the blood 24 hr. later but amounts ranging from 3.9 to 10.4 μ g. per g. were present in the liver. It is suggested that carotenoids may be present in blood combined with a specific constituent.

13. When 0.63 μ g. β -carotene had been given daily to rats for 3 days and they were killed on the fifth day, the blood contained no carotene but an average of 2.1 μ g. per g. was present in the liver. Ewes on a diet low in carotene and carotenoids contained in the liver 0.5 μ g. carotene and 0.4 μ g. xanthophylls per g. tissue. No carotenoids were found in the blood or ovaries. Cows fed on a diet high in carotene but low in carotenoids had average values for carotene of 435 μ g. per 100 ml. plasma, 20.6 μ g. per g. liver and 112.8 μ g. per g. ovary; the corresponding figures for xanthophylls were 16.9, 1.2 and 3.1. In male and female frogs the average carotene values for the liver were 14.7 and 8.5 μ g. per g., respectively; the corresponding values for xanthophylls were 7.7 and 3.7. The ovaries contained per g. 3.9 μ g. carotene and 10.5 μ g. xanthophylls but no carotenoids were detected in the blood. The authors suggest that differences between species in the absorption and deposition of carotenoids may be related to the presence or absence of appropriate protein receptors in the tissues and blood of the respective animals.

SAPUNOV, V. A. **Dinamika karotinoidov v krovi loshadei. [The dynamics of carotenoids in the blood of horses.]** *Konevodstvo*, 1953, No. 4, 24-27.

The level of carotene and total carotenoids in the blood of horses during winter stall feeding depended on the carotenoid content of the feed. In spring towards the end of stall feeding it fell with the decreasing amounts in the feed. Hard

N.A. and B., January 1954

work led to a low level of carotene in the blood. When large amounts of carotene were given, as in large feeds of carrots, large amounts were excreted in the faeces. The blood carotene value was higher in horses given a regular and abundant supply of carotene than in horses given carotene in large doses irregularly. On intravenous injection of carotene the level of blood carotene decreased or remained constant. When small amounts of carotene were given intravenously the level in the blood increased for a short time.—W. Hughes.

BAKER, F. H., MACVICAR, R., POPE, L. S. and WHITEHAIR, C. K. **Placental and mammary transfer of vitamin A and carotene by beef cows.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 571-574. [Dept. Animal Husb., Oklahoma Agric. and Mech. Coll., Stillwater.]

Hereford cows in the second or third month of pregnancy and given a ration low in carotene were divided into 4 groups, one given no supplement and 3 given supplements of 60 μ g. carotene per lb. bodyweight during lactation or during gestation or during both. The average vitamin A content of the liver in μ g. per g. dry matter of the 4 groups 6 months before parturition was 68.9, 70.6, 122.6 and 92.2, respectively; at parturition the average values were 5.7, 9.4, 20.6 and 14.3, and 3 months after parturition 1.7, 18.9, 7.4 and 23.4. The values for the livers of the calves of the respective groups at parturition was 4.2, 3.4, 2.6 and 3.0, and 3 months after parturition 1.9, 14.2, 5.1 and 22.3. The plasma vitamin A value in μ g. per 100 ml. fell from about 23 at 6 months before parturition to about 8 at 3 months before parturition for the first two groups, and rose at parturition to 11.3 and 15.1, respectively. The values for the plasma in the groups treated during gestation and during gestation and lactation fell from about 22 at 6 months before parturition to 10.1 and 14.2 at 3 months before parturition, and rose to 16.3 for both groups at parturition. During lactation the plasma values remained fairly constant. Plasma carotene levels, in μ g. per 100 ml., were 40.3, 45.8, 46.6 and 35.2 at 6 months before parturition, 11.6, 12.9, 31.1 and 25.8 at 3 months before parturition, 11.8, 10.3, 23.4 and 24.5 at parturition, 8.8, 52.6, 15.7 and 87.8 at 2 weeks after parturition, and 12.0, 43.0, 13.0 and 46.7 at 12 weeks after parturition. The vitamin A content of the colostrum declined rapidly and that of the milk remained almost constant during lactation.—R. J. Ward.

NARAYANAN, K. M., ANANTAKRISHNAN, C. P. and SEN, K. C. **Studies on vitamin A in milk. 6. The influence of continued intake of shark liver oil on the vitamin A content of milk and butterfat.** *Indian J. Dairy Sci.*, 1953, **6**, 67-74. [Indian Dairy Res. Inst., Bangalore.]

The milk yield, percentage fat and vitamin A potency of the milk remained unaltered when cows on a diet of high carotene content were given supplements of shark liver oil. On a diet of medium carotene content the shark liver supplement, equivalent to 100,000 I.U. vitamin A, caused a temporary increase in the vitamin A potency of the milk fat to 30 I.U. per g. from about 24. In a dry fodder period a supplement of 200,000 I.U. vitamin A in shark liver oil increased the vitamin A potency to 50 from about 24 I.U. per g. fat of milk from cows, and to 32 from 18 I.U. per g. fat of milk from buffaloes.

BHATIA, I. S. **Vitamin A content of cow's butterfat.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1953, **2**, 178-179. [Div. Quality Control, Central Food Technol. Res. Inst., Mysore.]

Vitamin A was estimated spectrographically in the butterfat of milk from 10 Desi cows. It varied from 17.5 to 61.0 I.U. per g. butterfat and tended to decrease as lactation progressed.—P. C. Jowsey.

339

BARABANSHCHIKOV, N. and FROLOVA, N. **Soderzhanie vitamina A v moloche koby.** [The vitamin A content of mare's milk.] *Konevodstvo*, 1953, No. 4, 43-45. [Zootekh. Inst. Konevodstva, Moscow.]

Estimation of vitamin A in mare's milk gave the following results in mg. per 100 ml.: April 1, 0; April 30, 0; May 30, 0.0832; June 30, 0.0786; July 30, 0.0640; August 30, 0.0650; September 30, 0.0510; October 30, 0.0320; November 30, 0.0125. The results show that mare's milk contained more vitamin A (0.0684 against 0.0351) than cow's milk when the animals were on pasture, but during stall feeding the cow's milk contained 0.0113 and mare's milk none. The vitamin A content of mare's milk obviously depends on the availability of the vitamin in the diet; it is therefore essential to ensure a sufficiency in the diet so that there will be some in the milk during stall feeding.—W. Hughes.

FAN, W. H. and HOU, H. C. Carotene contents of certain Nanking vegetables and fruits. *Chinese Med. J.*, 1953, **71**, 127-134.

Carotene was estimated in representative samples of the edible portion of 58 vegetables and fruits bought in the Nanking market. The material was ground with 50 per cent. KOH and extracted with ethanol; light petroleum was added and water. The light petroleum layer was removed, and the remainder was exhaustively extracted with light petroleum. The whole light petroleum extract was repeatedly extracted with 90 per cent. ethanol to remove xanthophylls. After further purification carotene was estimated in the light petroleum extract against a standardised solution of potassium dichromate. The results with the Chinese, English and Latin names of the plants are tabulated. The possible loss at the different stages of the method was tested by the recovery of added carotene, which amounted to from 82 to 100 per cent.—E. M. Hume.

342

CLARKE, M. F. A study of the carotene and crude protein content of orchardgrass (*Dactylis glomerata* L.) 2. Heritable variation. *Canad. J. Agric. Sci.*, 1953, **33**, 246-253. [Dept. Agronom., Pennsylvania State Coll.]

Open-pollinated clones and fifth generation inbreds (I_5) from a group of orchard grass plants were studied for heritable variation in the content of carotene and crude protein. All plants were given an initial clip to bring them into standard condition and were sampled when at the vegetative stage or when 6 in. high.

In two series which are described, with clones low and high in both carotene and protein, there was no significant difference between the mean values for the hybrid plants with I_5 clones, but with open-pollinated clones the hybrids showed a highly significant difference for both carotene and protein.—V. H. Booth.

SHAW, W. H. C. and JEFFERIES, J. P. The determination of ergosterol in yeast. 1. The ultraviolet absorption of purified ergosterol. 2. Determination by saponification and ultraviolet absorption spectroscopy. 3. Corrections for irrelevant absorption in solutions of ergosterol. 4. A short method based on ultraviolet absorption. *Analyst*, 1953, **78**, 509-514; 514-519; 519-523; 524-528. [Glaxo Labs., Ltd., Greenford, Middlesex.]

1. Ergosterol was converted into its benzoate, which after recrystallisation five times was hydrolysed. The resulting ergosterol, after recrystallisation, was used for the construction of ultraviolet absorption curves for use in the estimation of ergosterol in yeast.

2. Yeast was treated by boiling under reflux with 40 per cent. KOH; the extract after purification was treated with digitonin. The precipitate obtained was dissolved in alcohol and the solution was used for spectroscopic estimation of ergosterol. There was no difference in absorption due to digitonin.

3. The digitonin precipitation could be avoided by applying a four-point geometrical correction

procedure to allow for irrelevant absorption. If the amount of ergosterol present was small the correction gave only an approximate value, and accurate results were obtained only by the digitonin procedure.

4. In the final semimicro-method, saponification of a sample of yeast was followed by extraction of the unsaponifiable matter with cyclohexane. The extract was used for spectroscopic estimation at an absorption maximum of 282 $m\mu$. The digitonin precipitation was not employed, but the geometrical correction procedure for irrelevant absorption was used. The method was rapid, but a somewhat greater standard deviation and lower results were obtained than by the full digitonin method.

RAOUL, Y., LE BOULCH, N., CHOPIN, J., MEUNIER, P. and GUERILLOT-VINET, A. Données nouvelles sur les substances antirachitiques naturelles; leur présence dans les végétaux. [New data on natural antirachitic substances; their presence in plants.] *C.R. Acad. Sci.*, 1953, **237**, 439-440.

The new antirachitic substance previously obtained from fish liver oils (Abst. 2853, Vol. 23) was further investigated and compared with the

N.A. and R., January 1954

substance prepared from 2:4:2':4'-dicholestadiene with which it was first thought to be identical. The spectral absorption of both substances was in the ultraviolet between 250 and 265 $m\mu$. but the m.p. of the synthetic substance was 244° C. and of the natural one 136° C.; the molecular weights were 800 and 400. The two substances were thus steroids belonging to a double and a single series. Synthesis of both compounds was achieved. The active single substance and an inactive precursor were prepared from an ethanol extract of grass. Both the single and the double substance were regarded as carriers of Ca because of their selective capacity for fixing Ca reversibly *in vitro*.

WARD, R. J. and MOORE, T. **7-Dehydrosterol in the sexual organs of the rat.** *Biochem. J.*, 1953, **55**, 295-298. [Dunn Nutrit. Lab., Univ. Cambridge.]

In the course of a spectrophotometric study of the distribution of vitamin A in the male reproductive system of the rat, well-defined absorption bands at 293, 282, 272 and 262 $m\mu$. were detected. The bands were characteristic of 7-dehydrocholesterol or ergosterol, but the substance was not isolated in pure form so is referred to as 7-dehydrosterol. It was present in high concentration in the caput epididymis, corpus epididymis and preputial glands of adult male rats and in the bulbi vestibuli of female rats. Alterations in the diet of adult rats and deprivation of vitamin A had no effect on the presence of 7-dehydrosterol in these organs. It was found also in wild brown rats but not in immature rats or in the guineapig, rabbit or ram. An irradiated extract of rat preputial glands had antirachitic activity.

HANAHAN, D. J. and WAKIL, S. J. **Studies on absorption and metabolism of ergosterol- C^{14} .** *Arch. Biochem. Biophys.*, 1953, **44**, 150-158. [Dept. Biochem., Univ. Washington, Seattle 5.]

Ergosterol- ^{14}C was prepared from yeast incubated with acetic acid- ^{14}C . Adult rats were prepared with a lymph fistula or a bile fistula. Ergosterol- ^{14}C was administered orally or into the femoral vein. The radio-activity of certain tissues was estimated. Ergosterol was isolated from some of the material and estimated on the basis of its absorption at 282 $m\mu$.; the extent of its radio-activity was measured.

In 4 normal, adult rats given radio-active ergosterol orally, most of it was in the gut contents but small amounts were found in the liver, lungs, adrenal glands, spleen and urine. In rats with a thoracic duct fistula, treated in the same way, from 2.2 to 4.8 per cent. of the administered radio-

activity was found in the lymph; there was none in the liver. When radio-active ergosterol was given intravenously to normal rats, most of the radio-activity was in the liver with some in the lungs, spleen and intestinal contents, and a very small amount in the adrenal glands and urine. When radio-active ergosterol was given intravenously to rats with a bile fistula, 34 per cent. of the radio-activity passed into the bile within 72 hr.; a considerable amount of the remainder was in the liver with some in the lungs and spleen, and a little in the adrenal glands. None of the radio-activity of the bile could be identified as ergosterol. Evidence was obtained that none of the radio-active ergosterol was converted into cholesterol, but the exact chemical nature of the absorbed compound was not determined.—E. M. Hume.

349

CAUSERET, J. La vitamine D, facteur de régulation du pouvoir physiologique de fixation du calcium. [Vitamin D, the factor regulating the physiological capacity for calcium fixation.] *C.R. Acad. Sci.*, 1953, **237**, 104-106.

Male rats, aged from 40 to 50 days and weighing from 60 to 80 g., were fed on a diet of casein 18, arachis oil 9, starch 45, saccharose 24, salt mixture of Hubbel without $CaCO_3$ 2, and agar 2 per cent., with fat-soluble and water-soluble vitamins. Nine groups of 8 rats received additions of Ca ranging from 0.037 to 2.066 per cent., with Ca:P ratios ranging from 0.15 to 8.27. Each dietary group was divided into 2 so that 4 rats received 300 I.U. vitamin D per 100 g. ration and 4 received none. Ca was estimated in the food, urine and faeces and Ca retention was calculated. Without vitamin D, the graph relating Ca retention to intake was almost linear, retention increasing progressively with increasing intake. With vitamin D, retention was greater than without it for the smaller intakes, but for the 3 intakes greater than 0.466 per cent. there was no further increase in retention, which then became less than without vitamin D.

It is concluded that it is incorrect to call vitamin D a factor for the fixation of Ca; it is rather a factor which regulates the fixation.—E. M. Hume.

FROELICH, A. *Hautveränderungen und Krampfverhütung unter D₂-Hypervitaminose bei jungen Albinoratten. [Skin changes and prevention of cramp during administration of excess vitamin D₂ to young Albino rats.] Arch. exp. Pathol. Pharmacol.*, 1953, **219**, 512-517. [May Inst. Med. Res., Jewish Hosp., Cincinnati, Ohio.]

It had been found that acid fuchsin no. 72, injected into rats between 7 and 18 days old, induced cramps, often fatal. In older rats it did not do so unless injected into the brain, and it was concluded that the so-called *Blut-Gehirn-Schranke*, protecting the brain, became established only about the 21st day of life. Large doses of vitamin D, 1000 I.U. or more given daily for several days, prevented the occurrence of cramps, but theophyllin counteracted the protective action of vitamin D, a finding which is attributed to reduction of permeability.

Changes are described in the skin of rats given large doses of vitamin D before the 15th day of life. The skin became scaly and hairless, particularly on the top of the head, and there were deposits of Ca in it.

[The author of these experiments is dead. They were carried out in 1942-43, and specimen experiments are now published in celebration of the 80th birthday of Professor Otto Loewi.]—E. M. Hume.

354

SCHLUMBERGER, H. G. and BURK, D. H. *Comparative study of the reaction to injury. 2. Hypervitaminosis D in the frog with special reference to the lime sacs. Arch. Pathol.*, 1953, **56**, 103-124. [Dept. Pathol., Coll. Med., Ohio State Univ., Columbus.]

The paravertebral lime sacs of the frog are multilocular gland-like structures lined with cuboidal epithelium which probably secretes Ca into the sac. About 93 per cent. of the Ca in the sacs is CaCO₃ as the mineral aragonite.

The animals used were the leopard frog, *Rana pipiens*, and the African clawed toad, *Xenopus laevis*. They were received in good condition and not subsequently fed. Vitamin D₂ or D₃ was injected into the thigh muscles or coelomic cavity. Blood was taken from the heart under anaesthesia.

When the frogs were placed in a 0.8 per cent. solution of CaCl₂, X-ray photographs showed slow increase of Ca in the lime sacs, and appearance of some masses of Ca, found to be phosphate or carbonate, in the gut. It was concluded that Ca entered the body as swallowed water and not through the skin. With intramuscular injection of 30,000 U.S.P.U. or more of vitamin D₂ without added CaCl₂, Ca accumulated in the sacs within 2 or 3 weeks; in frogs kept in tap water it came from the bones. When vitamin D₂ was given after a sojourn in 0.8 per cent. CaCl₂ solution, accumulation of Ca in the sacs was rapid and prolonged. When vitamin D₂ in such large doses was given with or without added Ca in the water, osteoporosis occurred. Bone fractures in frogs heal with a large cartilaginous callus: vitamin D₂ did not accelerate its calcification. With large doses of vitamin D₂, 100,000 U.S.P.U. or more, with or without added Ca, metastatic calcification took place in the lumen of the renal tubules; the salt deposited was Ca phosphate. No definite changes could be detected in the parathyroid glands from giving vitamin D₂. No change in the serum Ca or P was detected on giving CaCl₂ or vitamin D₂ or D₃, but with both vitamin D₂ and CaCl₂, the level was significantly raised. The lime sacs are thought to play a part in stabilising the level of Ca in the serum. Vitamin D₂ was more active than vitamin D₃ in promoting filling of the lime sacs.

The African clawed toads are more primitive than the leopard frogs and appeared to have no lime sacs, although it was possible to raise the serum Ca value very materially. Osteoporosis and metastatic calcification were the same as in the frogs.

It is thought probable that the lime sacs act as a store for Ca in the absence of trabecular bone which has that function in higher vertebrates.

THOMPSON, J. J. and SMITH, N. C. **Exudative diathesis in chicks in New Zealand.** *Austral. Vet. J.*, 1953, **29**, 89-97. [Animal Indust. Div., Dept. Agric., New Zealand.]

During 1950 and 1951 outbreaks of an unidentified disease among chicks were reported from the Dunedin, Invercargill and Canterbury areas of South Island. Some of the outbreaks were severe with high mortality. Subsequent investigation appears to have established that the condition was a severe form of exudative diathesis like that recorded by Dam and Glavind in 1949 (Abst. 4131, Vol. 9). It could be prevented by the addition of *dl*- α -tocopherol to the ration. The amount of fish liver oil in the diet of the affected chicks varied from 1 to 3 per cent., and it is suggested that an additional precipitating factor may have been the presence of "heated" or mouldy wheat.

Vol. 24, No. 1

of normal and vitamin E-deficient hamsters. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 637-638. [Dept. Psychiat., Cornell Univ. Med. Coll., New York.]

Young hamsters were kept for from 4 to 5 weeks on a diet deficient in vitamin E. Histological studies showed that the muscles had become dystrophic. Slices of the gastrocnemius muscle and of the diaphragm from these animals and from others which had been given vitamin E throughout were incubated in a Krebs Ringer bicarbonate buffer solution, and the breakdown of protein was measured by the increase of amino-N in the fluid. For the gastrocnemius muscle of the deficient and normal hamsters, respectively, the difference between the readings after 15 and 60 min. was 27.9 and 33 μ g. N per 100 g. wet tissue. For the diaphragm the corresponding values were 25.8 and 32.0. Similar results were obtained with rabbits. The loss of muscle protein in vitamin E deficiency cannot therefore be explained by an increase in the rate of breakdown. A low rate of protein synthesis in the deficient animals seemed probable.

FERDMAN, D. L. and GRIGOR'EVA, V. A. **Intensivnost' obmena fosfornykh soednienii v mysh-tsakh krolikov pri eksperimental'noi myshechnoi distrofii (avitaminoze E.).** [Rate of exchange of phosphorus compounds in the muscles of rabbits during experimental muscular dystrophy (vitamin E deficiency).] *Dokl. Akad. Nauk. S.S.S.R.*, 1952, **85**, 863-866. [Inst. Biokhim., Akad. Nauk SSSR.]

Normal rabbits and rabbits deprived of vitamin E were given Na_2HPO_4 containing radio-active P. Two hr. later they were killed; the muscles were removed and the rate of uptake of P was estimated by measuring radio-activity, total P, water-soluble P, adenosinetriphosphate, inorganic phosphate and creatine phosphate. The rate of exchange of the several P compounds was considerably higher in the muscles of the dystrophic rabbits than in those of the normal animals. Additional experiments showed that the amount of radio-active P in the blood plasma of the two groups was similar and that the rate of uptake of radio-active P in the several P fractions from muscles of starved rabbits was somewhat lower than in those of normal animals.—W. Hughes.

ROSENKRANTZ, H. and MILHORAT, A. T. **Arginase activity in vitamin E-deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 57-59. [Dept. Med., Cornell Univ. Med. Coll., New York.]

Male rats in 3 groups of 30 animals each were given a diet deficient in vitamin E. One group was given a daily supplement of α -tocopherol and another was given L(+)-arginine monochloride, starting with a dose of 100 mg. daily and rising in 6 weeks to a maximum of 600 mg. Testicular changes were recorded from periodic biopsies. The arginase content of the liver and kidneys was estimated by the method of Kochakian (*J. Biol. Chem.*, 1945, **161**, 115). In about 70 per cent. of the deficient animals testicular degeneration was severe and was not prevented by the arginine supplement. The arginase content of the kidneys and livers in all the groups was the same.

CASSELMAN, W. G. B. Factors influencing the formation of ceroid in the livers of choline-deficient rats. 1. Dietary fats. 2. Dietary antioxidants. *Biochim. biophys. Acta*, 1953, **11**, 445-446; 446-447. [Banting and Best Dept. Med. Res., Univ. Toronto, Ont.]

1. Young rats were given diets lacking choline and containing 0.01 per cent. of added tocopherol.

One group received the diet without fat except for a supplement of methyl linoleate. The diets of the 6 other groups contained 10 per cent. of hydrogenated cottonseed oil of iodine value (i.v.) 12 or 36, or of cocoa butter i.v. 36, or of beef tallow i.v. 40, or of cottonseed oil i.v. 111, or of a mixture of 4 parts of cod liver oil with 6 parts of maize oil i. v. 125. Supplements of choline were given during the early stages of the experiment to prevent renal lesions. The rats were killed after receiving the diets for from 55 to 126 days, and the concentration of ceroid pigment in the liver was assessed by staining paraffin sections with Oil Red O. No difference was found in the degree of fatty infiltration between the several groups. After from 55 to 75 days the amount of ceroid in the livers of rats which had received no fat was graded as a trace, but after from 105 to 126 days the grading had risen to 2. In the groups given beef tallow or either of the hydrogenated cottonseed oils the grading was a trace at both times, and in those given cocoa butter 1. In the groups given the more highly unsaturated mixture of cod liver oil and maize oil, the livers contained much more ceroid, with a grading of 2 after from 55 to 75 days and 3 after from 105 to 126 days.

2. Three groups of male rats, of bodyweight from 180 to 200 g., were given a diet deficient in both choline and vitamin E. One group was fed to appetite without supplement; the other groups were limited to the amount of food eaten by the rats in the first group, but received a supplement of 0.05 per cent. α -tocopheryl acetate or of 0.1 per cent. methylene blue. A supplement of choline was given during the first 18 days to prevent renal lesions, and the rats were killed after from 52 to 62 days. In all 3 groups the rats failed to grow normally, and the degree of fatty infiltration of the liver was the same. The grading for ceroid was 3 in the group with no supplement, 2 in that given tocopherol and 1 in that given methylene blue. The findings support the view that ceroid is formed from tissue lipids which have accumulated in abnormal amount in conditions favouring auto-oxidation.—T. Moore.

HOVE, E. L. The relation of pyridine toxicity in rats to dietary vitamin E. *J. Nutrition*, 1953, **50**, 361-371. [Dept. Animal Husb., Alabama Polytech. Inst., Auburn.]

Young rats were given a diet which contained 10 per cent. casein, and supplemented by individual

vitamins. For some of the animals the supplements included *dl*- α -tocopheryl acetate, but others received no vitamin E. Pyridine was given to some as 1 per cent. of the diet, or in single injections of 0.5 or 1 ml. per kg. bodyweight. In the rats not given vitamin E, pyridine caused the death of 64 per cent. and produced liver lesions in 74 per cent., compared with only 16 and 20 per cent. of the rats given vitamin E. In additional groups of rats methylene blue gave considerable, and yeast nucleic acid slight, protection against pyridine. In measurements with Warburg's respirometer, pyridine accelerated the O_2 uptake of lard, olive oil, maize oil and cod liver oil. With lard $\alpha\alpha'$ -dipyridine also increased the O_2 uptake, but piperidine and nicotinate had no effect. Methylene blue reduced the increased rate of O_2 uptake caused in cod liver oil by pyridine. It is suggested that the toxicity of pyridine was due to its pro-oxidant activity, which caused the formation of small amounts of fatty acid peroxides in the body.

TEDESCHI, G. G. and DE CICCO, A. Azione anti-vitaminica E degli esteri succinico e acetico dell'*o*-cresolo. [Antagonistic action of succinic and acetic esters of *o*-cresol to vitamin E.] Azione del succinato di *o*-cresolo sulla ghiandola mammaria. [Action of the succinate of *o*-cresol on the mammary gland.] *Quad. Nutrizione*, 1952, **12**, 414-421; 422-428. [Ist. Fisiol. Gen., Univ. Rome.]

The succinate and acetate of tri-*o*-cresol were prepared. After preliminary experiments with rats and 2 rabbits, 10 pregnant rats were given a single oral dose of 25 mg. succinate or acetate; 7 gave birth to normal litters, 2 suffered resorption

and 1 gave premature birth to a dead litter. Eight female rats were injected with 25 mg. acetate or succinate and were then mated. When 2 were killed after 13 days they contained dead fetuses with abnormal placentas. The rest were killed 25 days after the first mating, when all contained litters in process of resorption. Six male rats were given 25 mg. succinate orally and 3 were given further doses 12 and 24 days later. They were killed at intervals up to 55 days, and the germinal epithelium showed signs of degeneration of typical vitamin E deficiency. Female rats given just before mating 24 mg. succinate and at the same time 5, 10 or 25 mg. α -tocopherol produced normal litters. In male rats given the same doses, the germinal epithelium was normal.

The methyl ether of *o*-cresol had no anti-vitamin-E activity.

Of 9 sexually immature female rats weighing about 70 g. and maintained on a normal diet, 3 received daily for 10 days a subcutaneous injection of 1 mg. α -tocopherol, 3 received the same with 20 mg. *o*-cresol succinate, and 3 received no treatment. They were then killed and the mammary tissue was investigated. The *o*-cresol succinate counteracted the effect of tocopherol in stimulating the development of the gland. In a similar experiment with sexually mature rats, *o*-cresol succinate caused hyperplasia of the connective tissue of the mammary gland and disturbances of the epithelium in the secretory region, which were counteracted with α -tocopherol. In pregnant rats treated in the same way the activity of the mammary gland in lactation was checked by *o*-cresol succinate and the effect was counteracted by α -tocopherol.

ROMBOUTS, J. E. The destruction of B vitamins by certain salt mixtures in purified rations.

J. Nutrition, 1953, **50**, 255-266. [Biol. Lab., Royal Netherlands Yeast and Spirit Factory, Delft, Holland.]

Purified diet, 6 kg., was prepared according to the formula of Rombouts and Querido (Abst. 4248, Vol. 16), 40 g. salt mixture being supplied as the U.S.P. formula (1936, U.S.P. XI, p. 479), or as that of Phillips and Hart (Abst. 1842, Vol. 5), or as 20 g. of each. Fresh batches of diet were required for the 3 groups of weanling rats receiving the diets after 16, 20 and 22 days, respectively.

Growth of rats in the first group was continuous and good; in the third, it had stopped after 20 days but was restored to normal when fresh food was given. In the second group, the rats lost weight after 18 days, and grew at a suboptimum rate when fresh food was given but died after about 5 weeks. Optimum growth could be obtained with the Phillips and Hart mixture when cod liver oil was mixed into the diet and 6 B vitamins were given orally twice a week. When the B vitamins were incorporated in the diet, most of the animals died in 5 weeks whether cod liver oil was given separately or in the diet. The pH value of the U.S.P. salt mixture, 5.4 in 2 per cent. suspension, was adjusted to 6.5 and that of the Phillips and Hart mixture, usually 6.3, to 5.4. Growth was still excellent with the U.S.P. mixture and much improved with the other. Omission of Zn and Cu from the mixture did not improve growth, and addition of these to the U.S.P. mixture had no harmful effect.

In further tests diet was prepared in advance so that the minerals of the Phillips and Hart mixture could react with the vitamins; rats then received the diet with a supplement of one of the 6 B vitamins employed. Growth was significantly greater in the group given vitamin B₁. When the diet was prepared with inclusion of only one of the B vitamins, the other 5 being given orally, growth was least when vitamin B₁ was the one mixed into the diet. It was apparent that vitamin B₁ was the most affected by the salt mixture of Phillips and Hart, and riboflavin the least. The effect may have been caused partly by the higher pH value in watery suspension.—V. R. Jackson.

MOSES, W. and JOSLYN, M. A. **The equivalence of thiamine and pyridoxine for a strain of *Saccharomyces cerevisiae*. 1. Effect on growth rate and carboxylase activity. 2. The loss of pyridoxine during growth and the sparing effect**

of thiamin transaminase activity. *J. Bacteriol.*, 1953, **66**, 197-203; 204-209. [Div. Food Technol., Univ. California, Berkeley.]

Experiments with a culture of brewery top yeast showed that vitamin B₁ and pyridoxine could serve alternatively as stimulant for growth. The nutritional conditions in which the equivalence occurred or failed to occur are described in detail. It was concluded, as the most probable explanation, that there is a reversible interrelationship between the two vitamins with pyrimidine as the key intermediate compound.—V. R. Jackson.

373

TRIBE, D. E. and GORDON, J. G. **Choice of diet by rats deficient in members of the vitamin B complex.** *Brit. J. Nutrition*, 1953, **7**, 197-201. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Thirty hooded rats of about 100 g. weight were divided into 5 groups. The first had the choice of a basal synthetic diet with or without B vitamins; the position of food pots and diets was changed daily. In the second group, the animals were deprived of B vitamins until signs of deficiency appeared and were then offered the choice of the same two diets. The third and fourth groups were treated like the first, except that the position of the diets but not of the food pots, or of the food pots but not of the diets, was changed daily. The fifth group received a complete diet.

The rats deprived of B vitamins showed a clear preference for the diet containing B vitamins, but it was apparent also from the results in the fourth group that they showed preference for a certain feeding place as well as for a diet. Normal rats showed a less obvious preference for the diet containing B vitamins.

With one exception all the rats were able to differentiate between the diets. Twelve normal human beings failed to do so.—V. R. Jackson.

374

WERTMAN, K., ROTUNDO, R. and YEE, R. **Blood and bone marrow study of vitamin-deficient rats.** *J. Nutrition*, 1953, **50**, 479-485. [Div. Bacteriol., Dept. Biol. Sci., Univ. Pittsburg, Pa.]

Male weanling albino rats received a purified basal diet containing *i*-inositol, *p*-aminobenzoic acid and 2-methyl-1:4-naphthaquinone, alone or supplemented with all B vitamins or all except vitamin B₁. Other animals received the complete diet with intake restricted to maintain weight at the level of the deprived.

Animals on the complete diet to appetite remained healthy and grew well. In the deprived, signs of deficiency appeared after 4 weeks, including failure to gain weight, paraplegia and convulsions and, in those deprived of all B vitamins, loss

N.A. and R., January 1954

of hair also. At this time total erythrocyte and leucocyte and differential cell counts and films of bone marrow were made.

Vitamin deficiencies and inanition caused leucopenia, but had no significant effect on the erythrocyte count of peripheral blood. The number of neutrophils per c.mm. was not appreciably changed, as there was a percentage increase of these cells. The percentage and number of lymphocytes per c.mm. fell. In general, the number of granulocytes did not differ significantly from that in the normal animals; the number of monocytes, eosinophils and basophils also was normal.

In the bone marrow of the animals deprived of vitamin B₁ or B complex vitamins there was relative granulocytosis with a corresponding increase in younger myeloid cells. In vitamin-deficient animals and animals with inanition there was a relative lymphocytopenia and a slight increase in granulocytes. The number of nucleated red cells was low in those deprived of vitamin B₁. The percentages of other types of cells were not significantly different from those in rats receiving full diet.—V. R. Jackson.

375

SAHASHI, Y. and IWAMOTO, K. **Biochemical studies on vitamin B₁₂. 6. Relation of vitamin B₁ and vitamin B₁₂ to energy metabolism in cattle.** *Proc. Japan Acad.*, 1953, 29, 33-35. [Lab. Biochem., Fac. Agric., Univ. Tokyo.]

Estimations of vitamin B₁ and B₁₂ in the blood, and red cell counts, were made on 2-year-old twin heifers, one of which was made to carry a load of 20 kg. for 4½ hr. on a treadmill while the other remained at rest. During the severe expenditure of energy there was a decrease in both vitamins in the blood with a fall in the red cell count and an increase in the size of the cells. The possible role of vitamins B₁ and B₁₂ in energy metabolism is discussed.—A. M. Copping.

DI RAIMONDO, F., MANNINO, N. and ORABONA, M. L. **Inibizione vitaminica dell'antibiosi per antagonismo metabolico. [Inhibition of antibiotics by vitamins through metabolic antagonism.]** Ricerche "in vitro" su *Staph. aureus* con terramicina e tirotricina. [Experiments in vitro with terramycin and tyrothricin against *Staph. aureus*.]

DI RAIMONDO, F., ORABONA, M. L. and ALBANO, O. **Ricerche in vitro su *Pasteurella aviseptica* con streptomycina e terramicina. [Experiments in vitro with streptomycin and terramycin against *Pasteurella aviseptica*.]** *Boll. Ist. sieroterap. milan.*, 1953, 32, 45-51; 52-57. [Ist. Clin. Med., Univ. Bari.] English summary.

Growth of *Staph. aureus* in vitro was almost

completely inhibited by a concentration of 3 µg. tyrothricin per ml. The inhibition was partly overcome by, per ml., vitamin B₁, riboflavin or pyridoxine 1 µg., nicotinamide 0.1 µg. or vitamin B₁₂ 0.01 µg. With terramycin, 5 µg. per ml., the inhibition was more completely overcome by the individual vitamins than with tyrothricin; a concentration per ml. of nicotinamide, pyridoxine or vitamin B₁₂ 1 µg., riboflavin or folic acid 0.1 µg., vitamin B₁ 10 µg., or *p*-aminobenzoic acid 100 µg., all had a considerable effect.

In similar experiments, inhibition of growth of *Pasteurella aviseptica* by a concentration of 5 µg. per ml. of terramycin was partly overcome by concentrations per ml. of nicotinamide, riboflavin or pyridoxine 1 µg., vitamin B₁ or folic acid 10 µg., vitamin B₁₂ 0.1 µg. or pantothenic acid 100 µg. The effect of streptomycin, 5 µg. per ml., was less easily overcome, but some effect was produced by, per ml., pyridoxine, folic acid, nicotinamide or riboflavin 1 µg., vitamin B₁₂ 0.1 µg., or vitamin B₁, *p*-aminobenzoic acid or Ca pantothenate 100 µg. With both drugs the effect of pantothenic acid was the weakest.—E. M. Hume.

L. and ALBANO, O. **Nutrizione e terapia antibiotica: ulteriori ricerche sulle interferenze tra vitamine del complesso B e penicillina nella infezione stafilococcica sperimentale. [Nutrition and treatment with antibiotics: further studies on antagonism between vitamins of the B complex and penicillin in experimental staphylococcal infection.]** *Boll. Ist. sieroterap. milan.*, 1953, 32, 118-123. [Ist. Clin. Med., Univ. Bari.] English summary.

In experiments with 355 mice a dose of *Staphylococcus aureus* in pig's gastric mucin, sufficient to kill about half the animals, was injected intraperitoneally. At the same time a protective injection of 500 units penicillin was given, and 3 hr. previously one of the B vitamins to be tested was injected. The protective action of penicillin was completely counteracted by pyridoxine (150 µg.), and almost completely by folic acid (150 µg.), nicotinamide (150 µg.) or vitamin B₁₂ (1.5 µg.). Vitamin B₁ (200 µg.), pantothenic acid (250 µg.) or *p*-aminobenzoic acid (250 µg.) exercised very little counteraction, and riboflavin (50 µg.) or biotin (10 µg.) none at all.—E. M. Hume.

PONZONI, R., GIBERTI, A. and SPAMPINATO, V. **Sulla morte precoce delle cavie in corso di trattamento aureomicinico. Tentativi di protezione con vitamine dei gruppi B e C e con cortisone. [Premature death of guineapigs being treated with aureomycin. Attempts at**

protection with vitamin B complex, vitamin C and cortisone.] 1. Ricerche batteriologiche. [Bacteriological investigations.]

GIBERTI, A., PONZONI, R. and SPAMPINATO, V. 2. Ricerche istologiche. [2. Histological investigations.] *Boll. Ist. sieroterap. milan.*, 1953, **32**, 239-245; 246-255. [Ist. Microbiol. Igiene, Univ. Modena.] English summary.

1. When 10 guineapigs of about 500 g. weight were given orally 25 mg. aureomycin they all died within 5 days. Daily injection, from the day before administration of aureomycin, of vitamins of the B complex, or of ascorbic acid and vitamin P, or of cortisone had no palliative effect.

2. Histological examination of the organs of guineapigs treated as described above showed that aureomycin caused degeneration and haemorrhagic lesions, especially in the liver, kidneys and adrenal glands, which were somewhat less severe, although fatal, in those treated with the vitamins or cortisone.—E. M. Hume.

379

GUGGENHEIM, K., HALEVY, S., HARTMANN, I. and ZAMIR, R. The effect of antibiotics on the metabolism of certain B vitamins. *J. Nutrition*, 1953, **50**, 245-253. [Lab. Nutrit., Hebrew Univ.-Hadassah Med. Sch., Jerusalem, Israel.]

Weanling male rats received a purified basal diet supplemented with limited amounts of vitamin B₁, riboflavin or pantothenic acid and with the other vitamins in adequate amounts, and were given aureomycin, penicillin, terramycin or streptomycin to the extent of 50 mg. per kg. diet. After 3 and 5 weeks faeces and urine were collected for 3 days and vitamin B₁ in the faeces, and riboflavin and pantothenic acid in the faeces and urine, were estimated.

All the antibiotics stimulated growth in rats partially deprived of riboflavin or pantothenic acid, but only penicillin and terramycin improved growth in vitamin B₁ deficiency. All the antibiotics increased urinary excretion of riboflavin and pantothenic acid; aureomycin, streptomycin and terramycin increased faecal excretion of pantothenic acid, penicillin that of riboflavin.

Penicillin, aureomycin and terramycin increased the amounts of all 3 vitamins in the livers of deprived rats; streptomycin increased riboflavin and pantothenic acid only. In diets with adequate amounts of the vitamin studied, no antibiotic affected the vitamin B₁ content of liver, but aureomycin and penicillin increased the urinary excretion and liver content of riboflavin and pantothenic acid. With adequate amounts of vitamins the antibiotics did not stimulate growth.

When the antibiotics were given subcutaneously to rats partially deprived of a vitamin they did

not stimulate growth or increase the vitamin content of the liver. It is concluded that the effect of antibiotics was due to direct action on the intestinal flora.—V. R. Jackson.

380

CALET, C., RERAT, A. and JACQUOT, R. Action d'épargne des antibiotiques pour quelques vitamines du groupe B. [Sparing action of antibiotics for some vitamins of the B group.] *C.R. Acad. Sci.*, 1953, **236**, 2340-2342.

Four groups of young rats received an adequate synthetic diet, or the diet with only 10 per cent. of the amounts of B vitamins, or the diet with low vitamins but supplemented by 0.016 per cent. procaine penicillin or 0.01 per cent. aureomycin. After 9 weeks, the average daily gain was for the 4 groups, respectively, 2.56, 1.06, 1.36 and 1.62 g. The antibiotics also improved efficiency of food utilisation compared with that of deprived rats, but not to equal the efficiency in rats with an adequate diet. The ratios of liver weight to total weight were increased by the antibiotics over that in normal and deprived rats. Estimation of B vitamins in the liver showed that antibiotics increased the concentration of vitamin B₁₂ but not of riboflavin or nicotinic or pantothenic acid. They increased the total vitamin contents in conditions of deficiency, over those of deprived animals.

It is considered that the favourable effect of antibiotics on the growth of deprived rats is due to their sparing action on the use of the vitamins.

BROWN, J. A., ROBBLEE, A. R. and CLANDININ, D. R. The use of penicillin in breeding rations. *Poultry Sci.*, 1953, **32**, 576-578. [Poultry Div., Univ. Alberta, Edmonton.]

In experiments lasting 336 days, penicillin, when added to 3 practical rations which differed in protein and energy content, had no influence on bodyweight, egg production, efficiency of feed utilisation, fertility or hatching capacity of the eggs. Storage of riboflavin in the liver was not affected.—E. M. Cruickshank.

382

BRIGGS, G. M., HILL, E. G. and CANFIELD, T. H. The need for choline, folic acid, and nicotinic acid by goslings fed purified diets. *Poultry Sci.*, 1953, **32**, 678-680. [Dept. Poultry Husb., Univ. Minnesota, St. Paul.]

Day-old goslings given for 2 weeks purified diets containing adequate amounts of the required vitamins grew as well as birds on a stock ration. When choline, nicotinic acid or folic acid was omitted from the purified diet, growth was retarded within 5 days, and paralysis occurred,

N.A. and R., January 1954

followed by death. Lack of nicotinic acid or choline caused paralysis of the legs, particularly of the hock joint; lack of folic acid caused cervical paralysis, which was cured by injection of pteroyl-glutamic acid.—E. M. Cruickshank.

THAYER, R. H. and DAVIS, J. P. **B-complex vitamin allowances for Oklahoma broiler rations.** *Oklahoma Agric. Exp. Stat. Bull.* No. B-393, March 1953, pp. 11. [Stillwater, Okla.]

New Hampshire chicks received a semi-purified diet or a practical commercial diet containing cereals, minerals, fat-soluble vitamins, vitamin B₁₂ and an antibiotic, each diet being supplemented by graded amounts of riboflavin, nicotinic, pantothenic and folic acids and choline. The chicks were kept in battery brooders and the growth rate was recorded for 4 and 8 weeks.

Satisfactory growth was obtained when the total vitamin content of the diet in mg. per lb. ranged from 5 to 6.5 for riboflavin, 8 to 16 for nicotinic acid, 5 to 6 for pantothenic acid, 1 to 1.5 for folic acid and 700 to 800 for choline. In selecting the amounts to be added the cost of the supplements and the nature of the ingredients were considered. When maize was the principal grain, the higher limit for nicotinic acid was preferred.

V. R. Jackson.

ROBBLEE, A. R. and CLANDININ, D. R. **The use of calcium pantothenate and biotin in practical poult starters.** *Poultry Sci.*, 1953, **32**, 579-582. [Poultry Div., Univ. Alberta, Edmonton.]

Of recent years a condition characterised by dermatitis, broken feathers, perosis, diarrhoea and high mortality has been seen in young poults which were receiving rations presumed to be adequate. In the present experiments addition to the breeder ration of calcium pantothenate or buttermilk had no effect on the incidence of the disease. Since the signs appeared to become more severe as the breeding season progressed, both early and late hatched poults were used for a test. They were given for 4 weeks a practical basal ration containing maize, wheat, oat and barley meals, wheat by-products, alfalfa meal, herring meal, meat scrap, soya bean meal, minerals and vitamins A and D with added riboflavin, nicotinic acid and choline. With this ration signs of deficiency appeared between 2 and 4 weeks of age. Addition to the ration of calcium pantothenate decreased mortality and improved growth in poults hatched in the early, but not in the late, part of the season, but the incidence of the other abnormalities was not reduced. A further

addition of folic acid was without effect, but a combination of calcium pantothenate and biotin greatly reduced the incidence of the disorder.

E. M. Cruickshank.

ADRIAN, J. Contingence ou autonomie de l'oeuf de poule vis-à-vis de l'équilibre vitaminique de la mère. Cas des surcharges en acide pantothenique et en niacine. [**Dependence or independence of the hen's egg on the vitamin balance of the hen. Test administration of pantothenic and nicotinic acids.**] *C.R. Acad. Sci.*, 1953, **237**, 273-274.

Six hens received for 2 weeks a diet containing per kg. 14 mg. Ca pantothenate and 100 mg. nicotinic acid, and then for 2 weeks a diet with 375 mg. Ca pantothenate and 1250 mg. nicotinic acid. The two vitamins were estimated in the eggs.

When the vitamin supplements were increased there was a 15 per cent. increase of the nicotinic acid content of the egg followed by a fall to the original value; pantothenic acid increased 3.5 times. During the first period the percentage of ingested nicotinic acid and pantothenic acid retained in the egg was 35 and 0.17, respectively, and during the second period 4.5 and 0.016. The maximum values obtained for the egg were 7 mg. per cent. for pantothenic acid and 0.1 mg. per cent. for nicotinic acid.—V. R. Jackson.

MOINUDDIN, M., POPE, A. L., PHILLIPS, P. H. and BOHSTEDT, G. **The effect of ration on the riboflavin, niacin, and vitamin B₁₂ concentration of blood and milk of sheep.** *J. Animal Sci.*, 1953, **12**, 497-506. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

Four groups of 10 ewes were given basal diets differing in protein and mineral composition during late gestation and throughout lactation. Blood samples were taken at parturition and again 6 weeks later, and milk samples and blood samples from lambs at intervals for the first 6 weeks. No significant difference was found in the values for nicotinic acid and riboflavin in the blood or milk of the ewes or the blood of their lambs. The content of riboflavin in the ewes' blood decreased as lactation progressed but that of nicotinic acid remained constant. The content of both vitamins decreased in the lambs' blood.

A year later the same 40 ewes were given diets with or without supplements of cobalt and

bonemeal, and the vitamin B₁₂ content of the blood and milk was examined. At parturition the vitamin B₁₂ content of the blood was about the same in all groups, but subsequently the values rose in the ewes having Co in the diet. The vitamin B₁₂ content of the lambs' blood was higher also when the ewes received Co and was related to a higher vitamin B₁₂ potency of the milk in groups having Co. When both Co and bonemeal were present in the diet the amount of vitamin B₁₂ in the blood appeared to be increased, but supplements of Ca and P did not affect the amount of vitamin B₁₂ in the blood.

The change in all 3 vitamins in the blood of lambs from birth to from 6 to 8 weeks of age is considered to be evidence of placental transfer. It is suggested that routine supplements of Co should be given to pregnant ewes in order to assure an adequate supply of vitamin B₁₂ for growth and haemopoiesis.—A. M. Copping.

SMITH, Q. T. and ALLEN, R. S. **B-Vitamin levels in the blood of young dairy calves fed a milk replacement diet with and without aureomycin.** *J. Dairy Sci.*, 1953, **36**, 593. *Proc.* [Iowa State Coll., Ames.]

389

BOMAN, T. J. **Microbiological assay of vitamin B complex including folic acid in buffalo milk.** *Indian J. Dairy Sci.*, 1953, **6**, 41-45. [Pub. Health Lab., Poona.]

B vitamins were estimated microbiologically in 10 samples of buffalo milk. Average values in $\mu\text{g.}$ per ml. were for riboflavin 1.02, nicotinic acid 2.6, biotin 0.133, pantothenic acid 1.5, vitamin B₁ 0.5, vitamin B₆ 3.25, *p*-aminobenzoic acid 26.75, and folic acid 5.5. Buffalo milk is, therefore, a good source of most of the B vitamins. Exposure of milk to diffuse light for 6 hr. reduced the riboflavin content to 0.48 $\mu\text{g.}$ per ml., and in sunlight it fell to 0.18.—V. R. Jackson.

390

THOMAS, K., PACE, J. K. and WHITACRE, J. **Effect of enrichment on the thiamine, riboflavin and niacin content of corn meal and grits as prepared for eating.** *Texas Agric. Exp. Stat. Bull.* No. 753, October 1952, pp. 30.

Yellow and white maizemeal and flour (grits) with the germ removed were enriched with commercial mixtures of vitamin B₁, riboflavin and nicotinic acid, and were made into bread, pone, spoonbread, mush and boiled or fried grits, by standard recipes. Vitamins were estimated before and after cooking the mixtures and the results were compared with those for non-enriched meal and grits.

Grits contained a negligible amount of vitamin B₁; enrichment increased the amount of riboflavin and nicotinic acid by 5 and 7 times, respectively. There were no differences in percentage retention of any of the vitamins during cooking of non-enriched and enriched meals or grits.

No vitamin B₁ was lost from mush or from grits boiled for 30 min., but further boiling for from 4 to 7 hr. caused the loss of up to one-third. Frying caused only a slight loss. In maize bread made with sweet or sour milk and small amounts of leaven, retention was from 84 to 89 per cent., the pH of the batter being from 5.4 to 6.2. With higher pH due to high leavening, only 7 per cent. was retained. In pone and spoonbread retention was high over the whole range of pH values used.

The compulsory enrichment of maizemeal and grits in Texas is recommended.—V. R. Jackson.

391

PACE, J. K. and WHITACRE, J. **Factors affecting retention of B vitamins in corn bread made with enriched meal.** 1. The relation of pH to the retention of thiamine, riboflavin, and niacin in corn bread. 2. Relation of crust and crumb and of baking utensil to retention of thiamine in corn bread. 3. Retention of thiamine in corn muffins made with commercial mixes and in corn bread made with self-rising meals. *Food Res.*, 1953, **18**, 231-238; 239-244; 245-249. [Dept. Rural Home Res., Agric. Exp. Stat., College Station, Tex.]

1. Procedures were as described by Thomas *et al.* (see preceding Abst.). Maizemeal without germ was enriched with vitamin B₁, riboflavin and nicotinic acid. Retention of the vitamins was studied during cooking of maize bread made to a standard recipe; the pH was varied in the uncooked batter made with sour milk by increasing the amount of soda, and in the breads made with sweet milk by varying the amount of baking powder.

The pH of bread rose during baking, the rise being greater with higher initial values. The retention of vitamin B₁ was best, from 80 to 89 per cent., when the initial pH was not more than 6 and the final pH was therefore not more than 6.6. Great variations in retention occurred when the pH of the batter was between 6 and 6.45; when the pH of the batter was 6.6 and that of the bread between 7.2 and 8.9, all the vitamin was lost. Excess of baking powder did not cause much loss of vitamin B₁ since the pH remained the same and the bread did not become alkaline. The percentage retention ranged from 82 to 85 per cent. for 3 types of baking powder. Loss appeared to be due only to increasing amounts of soda in the standard recipe.

Percentage retention of nicotinic acid was from 95 to 96 and of riboflavin 102.

N.A. and R., January 1954

2. Maize bread, muffins and sticks made from enriched meal by a standard sour milk recipe were baked for 30 min. at 215° C. in utensils of tin, aluminium, pyrex or iron. Crust and crumb were removed and the retention of vitamin B₁ was estimated by the thiochrome method in comparison with the uncooked batter.

The type of utensil had no effect on the amount of vitamin B₁ retained. The percentage of the products represented by crust was 30 for loaves, 40 for muffins and 68 for sticks. The average percentage retention of the vitamin was 85, 79 and 66, respectively, showing that the loss increased as the total surface area of the batch increased. The differences in retention are considered to be of practical importance and, where the dietary supply of the vitamin is a problem, loaves are preferable to muffins and muffins to sticks.

3. Maize bread and muffins were prepared from 5 brands of muffin "mix" and from one each of whole and bolted self-raising meal. Vitamin B₁ was estimated in the mixes, meals, batters and baked products.

The quality of the baked products varied considerably. The vitamin B₁ content of the mixes and meals also varied, the highest value being 10 times that of the lowest. Batters too showed a wide variation.

The percentage retention in muffins ranged from 31 to 74. As before, it was related to the pH of the batter and muffin, retention being poor in batters with high pH giving a value for the bread at or above neutral. Muffins made from meal enriched in the laboratory retained from 79 to 84 per cent. It appeared, therefore, that the baking powders used in the mixes were not as well balanced as those used in the standard recipes.

Maize bread made from sour milk and self-raising whole or bolted meal retained 80 and 83 per cent. of vitamin B₁, respectively. Corresponding values when sweet milk was used were 69 and 46.—V. R. Jackson.

392

SIMPSON, I. A., CHOW, A. Y. and SOH, C. C. **The distribution of thiamine and riboflavin in the mung bean; and the changes that occur during germination.** *Cereal Chem.*, 1953, **30**, 222-229. [Inst. Med. Res., Kuala Lumpur, Malaya.]

Samples of mung bean (*Phaseolus aureus*) were germinated for up to 48 hr. at about 28° C., about half the time in the dark and at no time in direct sunlight. Vitamin B₁ and riboflavin were estimated fluorimetrically in dormant beans and after 8, 20 and 48 hr. Photographic examination was made of 3 sections of the beans after treatment with ferricyanide by the method of Simpson (Abst. 3387, Vol. 21).

Vol. 24, No. 1

Both vitamins decreased during the initial stages of germination, but after 20 hr. vitamin B₁ had slightly, and riboflavin had greatly, increased above the amounts in the dormant bean. Photographic examination showed that vitamin B₁ was concentrated in the cells of the germ and adjacent cotyledons. During germination there was diffusion through the cotyledons, possibly through translocation by absorbed water with concentration in the cell wall of the young shoot. Riboflavin was more generally dispersed through the cotyledons with higher concentrations in the radicle; it appeared to develop in cells of the young shoot. Certain cells in the cotyledons, possibly those of the vascular bundles, were richer in both vitamins.—V. R. Jackson.

393

LEONG, P. C. **The nutritive value of coconut toddy.** *Brit. J. Nutrition*, 1953, **7**, 253-259. [Dept. Chem., Univ. Malaya, Singapore.]

Coconut toddy, the partly fermented sap of *Cocos nucifera*, is a popular beverage in south-east Asia and the central Pacific islands, and is believed, without much evidence, to be a good source of B vitamins.

Samples from a government toddy-shop in Singapore contained about 5 per cent. of alcohol by volume and had the following mean composition in g. per 100 ml.; ash 0.28, crude protein (N × 6.25) 0.22, crude fat 0.04, invert sugar 1.94, sucrose 1.13, acidity as acetic acid 0.42; the calculated energy value was about 270 Cal. per pint.

Since toddy contains live yeast cells and much of the vitamin B₁ and riboflavin in live yeast is not thought to be available to man (cf. Abst. 3607, Vol. 15), toddy was centrifuged and the yeast cells and the liquid portion were investigated separately. Vitamin B₁ was estimated by the thiochrome method, riboflavin by a modification of the fluorimetric method of Barton-Wright and Booth (Abst. 1073, Vol. 13), and nicotinic acid by that of Friedemann and Frazier (Abst. 1725, Vol. 20).

Nearly all the vitamin B₁ and 75 per cent. of the riboflavin were in the yeast cells, but the liquid contained 59, 96 and 70 per cent., respectively, of the nicotinic acid, Ca and Fe. The liquid and the cells from 100 ml. toddy contained, respectively, on the average, in µg., vitamin B₁ 0.3 and 23.6, riboflavin 2.7 and 8.1, nicotinic acid 218 and 151, Ca 460 and 21 and Fe 228 and 96; 100 and 40 per cent., respectively, of the Fe was ionisable. Fe is perhaps partly supplied by the containers.

It is concluded that a pint of coconut toddy supplies only negligible proportions of the daily human requirement of vitamin B₁, riboflavin and Ca, but about 10 per cent. of the requirement of nicotinic acid and Fe.—W. M. Deans.

VITAMIN B₁ (ANEURIN, THIAMINE)

394

MACCAGARO, G. A. and LUGLI, A. M. Premesse sperimentali al dosaggio della tiamina con un ceppo di *Escherichia coli*. [Estimation of vitamin B₁ with a strain of *Bacterium coli*.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 181-184. [Ist. Igiene, Univ. Pavia.]

A strain, K12, of *Bacterium coli*, incapable of growing without vitamin B₁, was selected. The test organism was grown on plates in an agar medium with minerals and glucose, in which cups 8 mm. in diameter were cut. The test organism was incorporated in the agar, and vitamin B₁ in different concentrations was introduced into the cups, round which the zones of multiplication could be measured. The lowest concentration of vitamin B₁ at which growth was visible was from 10⁻⁶ to 10⁻⁵ µg. per ml. The relation between the log of the concentration and the diameter of the zone of multiplication was linear for concentrations between 10⁻⁴ and 1 µg. per ml. With hydrolysates of casein, nucleosides, or the vitamin B complex without vitamin B₁, there was no growth.

E. M. Hume.

395

BANDELIN, F. J. and TUSCHHOFF, J. V. Colorimetric determination of thiamine in pharmaceutical products. *Anal. Chem.*, 1953, **25**, 1198-1200. [Res. Labs., Flint, Eaton and Co., Decatur, Ill.]

The method was found suitable for materials containing high concentrations of vitamin B₁, since dilution was not necessary. Ammonium reineckate precipitated vitamin B₁ from aqueous solution and in the presence of nicotinic acid, nicotinamide and pyridoxine, vitamin B₁ reineckate could be selectively precipitated in buffer solution at pH 4.5. The precipitated vitamin B₁ reineckate was dissolved in acetone and estimated by spectrophotometric measurement at 525 mµ. Accuracy was within ± 2 per cent.—R. Marshall.

396

COURTEIX, M. J. Sur le dosage de la vitamine B₁: précision de la méthode au thiochrome. [Estimation of vitamin B₁: precision of the thiachrome method.] *Ann. pharm. franç.*, 1953, **11**, 279-283. [Soc. des Usines Chim. Rhône-Poulenc, Lab. Recherches Anal., Vitry-sur-Seine.]

A study of the errors inherent in the making up of the solutions needed for the thiochrome estimation of vitamin B₁ (U.S.P. XIV and Pharmacopoeia Internat. I) and in the fluorimetric readings, visual or photo-electric, showed that these methods

cannot be used for work which requires that the potency found should be at least 98 per cent. of the potency claimed.—K. H. Coward.

397

PARTINGTON, H. and WATERHOUSE, C. E. The stability of aneurine hydrochloride in pharmaceutical preparations. *J. Pharm.*, 1953, **5**, 715-722. [Res. Dept., Bob Martin, Ltd., Southport.]

Vitamin B₁ hydrochloride in relatively dry media was stable for long periods, even for several years, at pH 4. A loss of about 10 per cent. in tablets of pH from 4.0 to 5.0 occurred soon after manufacture. In media of higher pH there was greater loss which, at pH 6.5, might amount over years to as much as 33 per cent. At higher pH values almost all the vitamin disappeared. Relatively high concentrations of Cu appeared to have little effect on the dry media when stored at room temperature even for long periods.

K. H. Coward.

398

FARRER, K. T. H. The thermal destruction of vitamin B₁. Studies with aneurin mononitrate. *Austral. J. Exp. Biol. Med. Sci.*, 1953, **31**, 247-254. [Res. Labs., Kraft Foods, Ltd., Melbourne.]

Vitamin B₁ as the mononitrate or hydrochloride was estimated by the Jansen thiochrome method in buffer solutions at 100° C. and also in yeast extract to which the mononitrate or hydrochloride was added so that the natural vitamin was about 5 per cent. of the total.

The mononitrate behaved similarly to the hydrochloride but was less stable in the buffer solutions.

Processed cheese, fortified with the mononitrate to provide 96 per cent. of the total vitamin, was stored at temperatures from 21° to 65° C. and estimations were made at intervals. The mononitrate appeared slightly more stable than the hydrochloride, but their behaviour was much the same.—V. R. Jackson.

SILIPRANDI, D. and CICCARONE, P. **The action of diphosphothiamine on glucose tolerance.** *Acta med. scand.*, 1953, **146**, 146-147. [Inst. Biol. Chem., Univ. Rome.]

Estimations of blood sugar were made at 20 min. intervals in normal rabbits fasted for 24 hr., after receiving 1 g. glucose per kg. alone or with 15 mg. diphosphothiamine per kg. or 0.5 I.U. insulin per kg., or both.

Glucose tolerance was significantly increased by diphosphothiamine but not as much as by insulin. Administration of both together suggested that the effect of insulin was enhanced.—V. R. Jackson.

404

RINDI, G. **Attività transaminasica di alcuni tessuti di ratti in avitaminosi B₁. [Transaminase activity of certain tissues of rats deprived of vitamin B₁.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 170-173. [Ist. Fisiol., Univ. Pavia.]

Of 3 groups of rats of from 50 to 60 g. weight fed on a diet deficient in vitamin B₁, 2 groups had vitamin B₁ added, of which one was fed to appetite and the other restricted to the consumption of the deprived group. The rats were killed after from 18 to 22 days. The glutamic-oxalacetic transaminase activity of homogenates of the liver, heart, muscles and brain was estimated in the conversion of a mixture of L-aspartate and ketoglutarate to oxalacetate and L-glutamate. The transaminase activity was high in the rats deprived, and restricted but not deprived, so that the effect was caused by inanition and not by deprivation.—E. M. Hume.

LORENZINI, R., BOSCHI, S. and BENEDETTI, A. **Azione catalitica della cocarbossilasi nei processi di trasmetilazione. [Catalytic action of cocarboxylase in transmethylation processes.]** *Acta vitaminol.*, 1953, **7**, 141-142.

[Ist Clin. Med. Gen., Univ. Modena.] French, English, German and Spanish summaries.

Administration of 5 mg. vitamin B₁ or of 10 mg. cocarboxylase to 5 adult rats on a normal diet caused similar increases in excretion of methyl-N¹-pyridine compounds in the urine. In man increased excretion of methyl derivatives was found after intramuscular injection of 50 mg. cocarboxylase or vitamin B₁.—A. M. Copping.

407

OGATA, K., SHIMIZU, T. and ENOKI, C. **Studies on the metabolism of acid-soluble and acid-insoluble phosphate compounds in the liver of normal and thiamine-deficient rats.** *J. Biochem., Tokyo*, 1953, **40**, 141–150. [Dept. Biochem., Sch. Med., Univ. Niigata.]

Comparable groups of rats weighing about 70 g. were given a complete synthetic diet, a diet lacking in vitamin B₁ or the diet with vitamin B₁ but restricted in amount to that eaten by the deprived group. When signs of severe deficiency appeared, all the rats were starved for 12 hr. and then given an injection of disodium phosphate containing ³²P one hr. before they were killed. The livers were immediately removed and the acid-soluble and acid-insoluble phosphates were fractionated.

The distribution of ³²P showed no apparent change except in the lipid fraction where the values were low in rats deprived of vitamin B₁. Analysis for distribution of relative specific activity in terms of ³²P, however, indicated that in the deprived rats there was a significant decrease in the rate of turnover of labile P in the adenosine-triphosphate and -diphosphate fractions and in the lipid ribonucleic and deoxyribonucleic acid P. Cure of the deficiency by administration of vitamin B₁ restored the distribution of ³²P in the liver to some extent, but not completely in respect of the acid-insoluble fractions.—A. M. Copping.

Even when grave neurological signs of vitamin B₁ deficiency were present, the rate of conduction and action potential were normal in the sciatic nerve.—I. Leitch.

410

WAIBEL, P. E., CRAVENS, W. W. and BAUMANN, C. A. **Effect of dietary antibiotics on the growth of chicks receiving suboptimum amounts of thiamine by mouth or by injection.** *J. Nutrition*, 1953, **50**, 441–450. [Dept. Poultry Husb., Coll. Agric., Univ. Wisconsin, Madison.]

Day-old chicks received for from 11 to 28 days the vitamin-B₁-deficient diet described by Robblee *et al.* (Abst. 3767, Vol. 18), carbohydrate being either sucrose or dextrin, supplemented orally by 1.0, 1.5 or 6.0 µg. vitamin B₁ per g. diet. With each dose one group received no further supplement, and another got 35 p.p.m. aureomycin or 15 p.p.m. penicillin. With the largest amount of vitamin B₁, the antibiotics increased growth by 9.5 per cent., and with 1.5 µg. per g. growth was increased by 50 per cent. by aureomycin and 69 per cent. by penicillin; with 1.0 µg. per g. the increase was 45 and 57 per cent., respectively, and the survival time also was increased. Utilisation of feed was more efficient when antibiotics were given. A mixture of penicillin, aureomycin, bacitracin and streptomycin was as effective as penicillin alone. The effects were not observed when vitamin B₁ was given subcutaneously, and differences in weight between the groups were much less.

Replacement of 1 per cent. carbohydrate in the diet by glycerol improved the stability of vitamin B₁ in the diets. It is concluded that vitamin B₁ was used as efficiently from the diet as when injected if losses caused by instability before ingestion or by the activity of the intestinal flora were avoided. As much as 5 per cent. glycerol had no adverse effect on the growth of the chicks or their efficiency of feed utilisation.

CACIOPPO, F. **Comportamento della cocarbossilasi (APP) nelle uova di pollo durante il periodo di incubazione. [Behaviour of cocarboxylase (APP) in hen's eggs during incubation.]** *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1966–1968. [Ist. Chim., Fac. Med., Univ. Naples.]

It had been shown previously that the content of vitamin B₁ in the hen's egg declined rapidly on incubation (Abst. 4222, Vol. 23). Cocarboxylase was estimated by the method of Westenbrink (Abst. 2936, Vol. 11) in 94 eggs of White Leghorn hens before and at intervals up to the 18th day of incubation. The content of cocarboxylase was low before incubation but immediately increased to an extent corresponding with the great decrease in free vitamin B₁. From that point of maximum increase it decreased gradually, but even by the 18th day was still considerably higher than before incubation.—E. M. Hume.

- SARACOGU, S. The thiamine content of Turkish wheats and corresponding bulgurs. *Cereal Chem.*, 1953, **30**, 323-327. [Fac. Sci., Univ. Ankara, Turkey.]
- Twenty-eight varieties of hard, soft and mixed

wheats and of *bulgurs* made from them were collected in different regions of Turkey from 1947 to 1951, and estimations were made of moisture and of vitamin B₁ by the thiochrome methods. *Bulgur* is prepared from wheat grain by washing, boiling to gelatinise the starch, air-drying, crushing and, usually, winnowing to remove the hulls and sieving of the fine parts after crushing.

Wheat and *bulgur* contained 9.2 per cent. moisture. The vitamin B₁ content of wheat ranged from 3.11 to 5.04 μg . per g. with average 3.89 and of *bulgurs* from 1.44 to 3.57 with average 2.83. The figures are expressed on a basis of 14 per cent. moisture. The percentage of vitamin B₁ lost during conversion of wheat to *bulgur* ranged from 8.9 to 42.4, average 27.3. The greatest loss, averaging 22.6 per cent., occurred in the boiling, partly by destruction and partly by leaching, and was influenced by the variety, the proportions of wheat and water, the pH value, and the duration and manner of boiling. The fine fraction, removed in some regions by sieving, amounted to 10 per cent. and was the portion richest in vitamin B₁. The weight of the hulls was negligible compared with that of the grain, so that their removal caused little loss of vitamin. The hulls contained 3.18 μg . per g.

Measures for producing *bulgurs* of high vitamin B₁ content, including enrichment, are discussed.

- CLARKE, M. F. Media used for microbiological assay of riboflavin using *Lactobacillus casei*. Method of assay and confidence limits attainable. *Anal. Chem.*, 1953, **25**, 1247-1252. [Dept. Chem., Med. Coll. Virginia, Richmond.]
- A series of media were obtained by modifying 3 standard media, those of Greene and Black, U.S.P. and Roberts and Snell. The constituents varied were glucose content, growth stimulants and buffer.

Dose-response curves for the modified media are compared with those for the original media. For certain of the modified media there exists a linear relationship between response (titratable acidity) and the logarithm of the dose over a wide range of dose. This permits a statistical analysis of the standard curves to be made by established methods and results of such analyses are given for 4 of the most promising media and used to assess their relative merits.

Concentrates were assayed by each of the 4 media in turn and results are given for one such assay on a given sample of Sirup of Pantabee.

Vol. 24, No. 1

Confidence limits for potency are given. Agreement between values obtained with the different media was good.

In a final discussion, previous work is reviewed and the advantages of the new media are urged.

- HERRERA AVALOS, T. Valoración microbiológica de la riboflavina. [Microbiological estimation of riboflavin.] *An. Fac. Farm. Bioquím., Lima*, 1951, **2**, 66-70. [Lab. Bioquím. Gen., Univ. Nac. Mayor de San Marcos, Lima.]

Values were determined microbiologically for the riboflavin content of blood from 28 normal subjects, 32 samples from a blood bank and a dispensary, and from 10 patients. The range for the healthy was from 0.22 to 0.30 μg . per ml. and for the sick from 0.24 to 0.35.—I. Leitch.

417

- POVOLOTSKAYA, K. L. and SKOROBOGATOVA, E. P. Sopotavlenie khimicheskogo i mikrobiologicheskogo metodov opredeleniya riboflavina v rastitel'nom materiale. [Comparison

of chemical and microbiological methods for estimating riboflavin in plant materials.] *Biokhimiya*, 1953, 18, 79-88. [Vses. Nauch-Issled. Vitamin. Inst., Moscow.]

It has been shown experimentally that when a fluorimetric method is used for estimating riboflavin, it is essential that the fermentation stage is not omitted as is done in the methods described by Hoffer, Alcock and Geddes (Abst. 308, Vol. 15), by Arnold (Abst. 3203, Vol. 15) and in *Methods of Vitamin Assay* (Abst. 2976, Vol. 21). To determine the extinction point of the fluorescence by addition of sodium hydrosulphite is particularly important. A solution of riboflavin of known concentration estimated independently should be used as a standard. When the microbiological method used is that of Snell and Strong (Abst. 2944, Vol. 9) incubation should be continued for 48 hr. after inoculation. Centrifuging of the seeded material can be replaced by simple decantation. Good results were obtained with both acidimetric and turbidimetric methods but acidimetry is recommended. Riboflavin was estimated by chemical and microbiological methods in a number of materials and good agreement of the results was obtained. The results indicated that it is only with plant materials rich in pigments, such as the dog rose or pollen, that it is essential to use microbiological methods.—W. Hughes.

418

ALBERT, A. Quantitative studies of the avidity of naturally occurring substances for trace metals. 3. Pteridines, riboflavin and purines. *Biochem. J.*, 1953, 54, 646-654. [Dept. Med. Chem., Austral. Nat. Univ., Canberra.]

The avidities were recorded, in the form of stability constants of natural and synthetic pteridines, riboflavin, some natural purines, and 8-hydroxyquinoline and its sulphonic acid derivative, for ions of bivalent heavy metals. These substances all combined with metals through a hydroxyl group *peri* to a ring nitrogen atom, the avidity being usually in a graded and descending series from Cu through Ni, Co, Fe, Mn to Mg. Two different patterns were demonstrated in the stages of combination. Riboflavin appeared to have a relatively high avidity for ferrous iron and the fact is discussed in relation to association of metallic ions with enzymes containing this vitamin. Riboflavin was not reduced by ferrous and did not combine with ferric iron. High affinity for Fe was shown also by the purines, especially guanosine. Adenosine with no acidic group had no affinity for metals. Pteroylglutamic acid had a low affinity for Cu; in the lower pH ranges it formed highly insoluble salts with all the metals.

The colours of the complexes are described.

V. R. Jackson.

GIROUD, A., LÉVY, G. and MARTINET, M. Les cataractes foetales après thyroxine sont-elles liées à une carence. [Are foetal cataracts after thyroxine related to a deficiency?] *C.R. Soc. Biol.*, 1953, 147, 402-404.

Female rats received a standard basal diet and, after 9 days of gestation, 0.5 mg. thyroxine daily. They were killed after 21 days and pantothenic acid and riboflavin were estimated in the livers.

There was no difference in pantothenic acid content between livers from normal pregnant rats and those receiving thyroxine but in the latter group there was a considerable fall in riboflavin. It is concluded that the previously reported occurrence (Giroud and Rothschild, *Bull. Soc. Ophthal. France*, 1951, p. 543) of foetal cataract when the mothers had received thyroxine may have been due to induced riboflavin deficiency although in tests designed to produce them no eye lesions appeared in the mother or foetus.—V. R. Jackson.

DE BASTIANI, G., SPERTI, L. and ZATTI, P. Azione diabetogena della vitamina B₂ nel ratto albino. [Diabetogenic action of riboflavin for the albino rat.] *Boll. Soc. ital. Biol. sper.*, 1953, 29, 229-231. [Ist. Fisiol., Univ. Padua.]

Of 3 groups each of 30 rats weighing about 150 g., riboflavin was given to one intravenously and to one intraperitoneally in a single dose of 40, 60 or 80 mg. per kg. bodyweight. Blood sugar was estimated in a tolerance test with 5 g. glucose per kg. bodyweight. The third group received 100 mg. riboflavin by intramuscular injection daily for 10, 15 or 20 days. Most of the rats given 80 mg. by intravenous or intraperitoneal injection died. A few of the survivors injected intravenously failed to show any effect but the majority showed signs of diabetes including changes in the pancreas. Of the survivors injected intraperitoneally none showed signs of diabetes. The rats given daily intramuscular injections of 100 mg. riboflavin per kg. bodyweight showed a steadily rising value for the fasting blood sugar which gradually declined on cessation of treatment with riboflavin.—E. M. Hume.

NICOTINIC ACID (NIACIN)

424

JOHNSON, B. C. and LIN, P. H. Nicotinic acid metabolism. 1. The use of paper chromatography in the study of nicotinic acid metabolism.

LIN, P. H. and JOHNSON, B. C. 2. The metabolism of radioactive nicotinic acid and nicotinamide in the rat. *J. Amer. Chem. Soc.*, 1953, **75**, 2971-2973; 2974-2977. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

1. Nicotinic acid and its metabolites were separated on paper strip chromatograms with a solvent system of water-saturated *n*-butanol and acetone. The spots were detected by the CNBr reaction, by fluorescence, by spectral absorption with a Beckman spectrophotometer, and by bio-autographic and radio-autographic methods. The technique proved satisfactory for identifying excretion products of nicotinic acid in the urine of man and the rat, pig, guinea-pig, lamb and calf.

2. Nicotinic acid and nicotinamide labelled with ¹⁴C in the carboxyl group were given by intraperitoneal injection to 12 rats in glass metabolism cages. Urine and faeces were collected for 48 hr. and the animals were killed and the residual radioactivity in the carcass was measured. Very little radioactivity was found in the faeces; from 23 to 30 per cent. of the total injected remained in the carcass, and from 43 to 70 per cent. was in the urine. Of the radioactivity in the urine, 60 per cent. was present in nicotinuric acid after injection of nicotinic acid; a compound resembling N¹-methylnicotinamide accounted for 65 per cent. of the ¹⁴C excreted after nicotinamide. In the urine of rats given nicotinic acid at least 7 radio-active metabolites were present and at least 9 in the urine of rats given nicotinamide. A metabolite hitherto unidentified appeared after both nicotinic

acid and nicotinamide and followed N¹-methyl-2-pyridone-5-carboxylamide closely on the paper chromatogram.

¹⁴C was found in CO₂ expired by the animals, showing that decarboxylation of nicotinic acid and even more readily of nicotinamide occurred in the animal body.—A. M. Copping.

JANES, R. G. Certain metabolic effects of niacin and Priscoline. *Amer. J. Physiol.*, 1953, **174**, 46-48. [Dept. Anat., Coll. Med., State Univ. Iowa, Iowa City.]

The effects were compared of nicotinic acid and of a vasodilator substance, Priscoline, on the liver glycogen and acetone excretion of adult rats. The animals were given daily injections of 7 ml. physiological salt solution alone or with 35 mg. nicotinic acid or 20 mg. Priscoline during 5 days without food. Urine was collected throughout the period and liver and muscle were analysed at the end of the experiment. Both nicotinic acid and Priscoline raised the excretion of acetone bodies. With nicotinic acid the glycogen content of the liver rose and with Priscoline it fell. There was no apparent correlation between urinary excretion of ketones, and fat in the liver or muscle, or liver glycogen. The amount of N in the urine was above normal in both groups. It seemed that although both substances increased excretion of ketones their metabolic effects were different.—A. M. Copping.

427

COSTABILE, L., SCALA, E., SCARDI, V. and VIRGILIO, A. Formazione dei piridin-nucleotidi da triptofano e da amide nicotinica nelle emazie umane *in vitro*. [Formation of pyridine nucleotides from tryptophan and from nicotinamide by human red cells *in vitro*.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1850-1852. [Ist. Chim., Fac. Med., Univ. Naples.]

The amount of pyridine nucleotides synthesised by washed human red cells incubated at 37° C. in Ringer phosphate solution was increased many times by addition of nicotinamide but not of tryptophan or vitamin B₆ or both.—E. M. Hume.

428

CASTRO BARAHONA, J. Acción de la nicotinamida sobre la glucemia normal del conejo. [Effect of nicotinamide on the normal blood sugar of the rabbit.] *An Fac. Farm. Bioquím., Lima*, 1951, **2**, 498-503. [Lab. Farmacol., Univ. Nac. Mayor de San Marcos, Lima.]

Injection of from 0.005 to 0.020 mg. nicotinamide per kg. bodyweight into 7 male and 5 female rabbits of about 2 kg. weight caused a fall in the blood sugar value. The decrease was most marked after from 2 to 3 hr., and was greater in males than in females. The effect disappeared within 6 hr.—A. M. Copping.

429

NELSON, T. S. and SCOTT, H. M. Niacin deficiency in the chick as influenced by antibiotics. *Poultry Sci.*, 1953, **32**, 601-604. [Illinois Agric. Exp. Stat., Urbana.]

In chicks given a purified basal diet containing only 0.48 mg. nicotinic acid per kg. with dextrin or sucrose as the carbohydrate, viability and growth were poor and were not influenced by supplements of aureomycin or penicillin. Growth was significantly improved by supplements of 15 mg. nicotinic acid per kg. diet, but the incidence of perosis was high, with and without antibiotics, and irrespective of the carbohydrate given. Growth was further stimulated by increasing the amount of nicotinic acid to 50 mg., and perosis was almost eliminated. With either amount of nicotinic acid, aureomycin or penicillin significantly increased the growth response, particularly when the diet contained sucrose.—E. M. Cruickshank.

430

PEPPER, W. F., SLINGER, S. J. and MOTZOK, I. Effect of aureomycin on the niacin and man-

ganese requirements of chicks. *Poultry Sci.*, 1953, **32**, 656-660. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Groups of chicks received for 4 weeks diets containing all combinations of 10, 30 and 50 p.p.m. Mn and 9, 18 and 27 mg. nicotinic acid per lb., with or without 25 p.p.m. aureomycin. On all diets aureomycin increased growth and efficiency of feed utilisation but the response was relatively small on the diet containing 10 p.p.m. Mn and 9 mg. nicotinic acid. The results showed that aureomycin improved the utilisation of both Mn and nicotinic acid. When the diet contained 10 p.p.m. Mn combined with 9, 18 or 27 mg. nicotinic acid the incidence of perosis at 4 weeks of age was 60, 45 and 65 per cent., respectively. In the presence of aureomycin the corresponding figures were 35, 5 and 15. The weight of the small intestine and caeca increased significantly with increase in the Mn content of the diet. Aureomycin reduced the weight of the small intestine and slightly, but not significantly, increased the caecal weight. The requirement for nicotinic acid is considered to be more than 18 mg. per lb. feed and that for Mn more than 30 p.p.m.—E. M. Cruickshank.

431

SCOTT, M. L. Prevention of the enlarged hock disorder in turkeys with niacin and vitamin E. *Poultry Sci.*, 1953, **32**, 670-677. [Cornell Univ. Agric. Exp. Stat., Ithaca, N.Y.]

In turkey poultts receiving a diet containing from 2 to 4 per cent. cod liver oil, a high incidence of enlarged hocks occurs, which can be prevented by supplements of dried brewer's yeast. Since such poultts exhibit creatinuria and reduced muscle creatine, but do not respond to supplements of vitamin E alone, experiments were undertaken to ascertain what deficiencies were involved. The results showed that both nicotinic acid and vitamin E were necessary to prevent the enlarged hocks which develop on the basal diet of Scott (Abst. 1449, Vol. 22). Supplements per lb. of diet of at least 20 mg. nicotinic acid and 5 mg. α -tocopheryl acetate were required for complete prevention but, if the diet contained 1 per cent. of dried brewer's yeast or a suitable anti-oxidant, 2.5 mg. tocopherol were sufficient. It is suggested that brewer's yeast prevents the condition through its high content of available nicotinic acid and the presence in it of an anti-oxidant which protects vitamin E in the diet or in the body or both.

E. M. Cruickshank.

VITAMIN B₆ (PYRIDOXINE, ADERMIN)

432

NOVAK, A. F., GAMA, A. R., LINZZO, J. A. and RUBLOFF, E. B. **Factors affecting the microbiological assay of pyridoxine in multivite products.** *J. Amer. Pharm. Assoc.*, 1953, **42**, 581-583. [Res. Labs., Nutrilite Products, Inc., Buena Park, Calif.]

It was found necessary to supplement Difco Bacto Pyridoxine Assay Medium with vitamin B₁ when the pyridoxine content of crystalline multivitamin preparations was estimated with *Neurospora sitophila* A.T.C.C. 9276. Certain plant concentrates were found to contain another substance necessary for growth of the organism. It was distinct from vitamin B₁, folic acid, biotin, *p*-aminobenzoic acid, vitamin B₁₂, riboflavin, nicotinic acid and inositol.—K. H. Coward.

433

HEYL, D., LUZ, E., HARRIS, S. A. and FOLKERS, K. **Chemistry of vitamin B₆. 10. Some homologs of the vitamin B₆ group. 11. Homologs of 4-desoxy-pyridoxine.** *J. Amer. Chem. Soc.*, 1953, **75**, 4079-4080; 4080-4081. [Res. Labs., Merck and Co., Inc., Rahway, N.J.]

434

BEARE, J. L., BEATON, J. R. and MCHENRY, E. W. **Studies on vitamin B₆. 3. Carcass composition of the vitamin B₆-deficient rat.** *J. Biol. Chem.*, 1953, **202**, 589-595. [Dept. Pub. Health Nutrit., Univ. Toronto.]

When rats of average initial bodyweight 115 g. were given purified diets containing 20 per cent. of casein and 20 per cent. of maize oil, deprivation of vitamin B₆ and administration of deoxypyridoxine for 21 days produced typical skin lesions, and analysis of the carcasses showed a decrease of crude fatty acids with a slight increase in protein and water content, in comparison with pair-fed rats given vitamin B₆. Deprivation of vitamin B₁ in a similar experiment had an effect on body composition similar to lack of vitamin B₆. In a further experiment male rats of 240 g. and females of 181 g. were given diets without or with 5 or 20 per cent. of maize oil, with or without vitamin B₆. Again it appeared that animals deprived of vitamin B₆ were unable to increase the crude fatty acid content of the body with increasing intake of fat, and both male and female rats showed the same low content of fatty acids when deprived of vitamin B₆. With the inclusion of fat in the diet severe skin lesions did not occur in these older rats deprived of vitamin B₆.

A. M. Copping.

435

CALDWELL, E. F. and MCHENRY, E. W. **Studies on vitamin B₆ and transamination in rat liver.** *Arch. Biochem. Biophys.*, 1953, **45**, 97-104. [Dept. Pub. Health Nutrit., Univ. Toronto.]

The transamination of aspartic acid and of alanine to glutamic acid was studied in the livers of rats having diets containing 5, 20, 50 or 94 per cent. of casein, with or without vitamin B₆. The lowering effect of deprivation of vitamin B₆ on liver transaminases was more marked when the protein content of the diet was substantially greater or less than 20 per cent. When food intake was restricted the activity of the enzymes was increased if vitamin B₆ was given. In rats deprived of vitamin B₆ it was less, the decrease being most marked on the diet with only 5 per cent. casein. The transamination of alanine appeared to be more sensitive to changes in the diet than that of aspartic acid. In some experiments male and female rats were studied separately and males showed higher transaminase activity. In rats deprived of vitamin B₁ but having vitamin B₆, the severe inanition associated with vitamin B₁ deficiency caused a rise in the transaminase activity of the liver. The results are discussed in relation to others reported previously (Abst. 439, Vol. 24).

A. M. Copping.

436

CALDWELL, E. F. and MCHENRY, E. W. **Desoxy-pyridoxine and liver transamination in the rat.** *Arch. Biochem. Biophys.*, 1953, **45**, 466-467. [Dept. Pub. Health Nutrit., Sch. Hyg., Univ. Toronto.]

Albino rats received a diet containing 20 per cent. casein and no vitamin B₆. They were divided into 2 groups, one receiving 100 µg. deoxypyridoxine daily, and the other the basal diet only but with intake restricted to that of the first group. After 4 weeks the rats of the first group had severe dermatitis typical of vitamin B₆ deficiency and a much lower bodyweight. The rats were then fasted for 45 hr. and killed, and the transaminase activity of the liver was estimated. There was no significant effect on the aspartic-glutamic acid reaction but there was a great increase in the rate of alanine-glutamic acid transamination in the rats with dermatitis.

It is suggested that the presence of dermatitis was not related to alterations in the amount of transaminases.—V. R. Jackson.

437

LENTI, C. and GRILLO, M. A. **Attivazione con piridoxalfosfato, glutatione, adenosin-5-fosfato e adenosina del processo di formazione di**

acetaldeide dalla d, l-treonina nel fegato. [Activation by pyridoxal phosphate, glutathione, adenosine-5-phosphate and adenosine of the formation of acetaldehyde from dl-threonine in the liver.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1970-1973. [Ist. Chim. Biol., Univ. Turin.]

The formation of acetaldehyde from dl-threonine by extract of fresh rat liver or of acetone liver powder was considerably increased in presence of pyridoxal phosphate. The reaction was inhibited in presence of hydroxylamine, but the inhibition was counteracted by excess of pyridoxal phosphate. In the formation of acetaldehyde from threonine by glutathione and to some extent, by extract of fresh liver but not of acetone powder, pyridoxal phosphate could be replaced by adenosine-5-phosphate or adenosine, but not by adenosinedi- or -triphosphate, adenine or ribose.—E. M. Hume.

438

THOMPSON, R. Q. and GUERRANT, N. B. Effect of dietary protein and vitamin B₆ on hepatic thionase activity. *J. Nutrition*, 1953, **50**, 161-174. [Dept. Agric. Biol. Chem., Pennsylvania State Coll., State College.]

Weanling albino, black and piebald rats were given purified diets containing 20 or 40 per cent. casein with or without vitamin B₆ in the vitamin supplements. A third group received the diet with 20 per cent. casein and added DL-methionine and L-cystine. Animals in each group were killed at the beginning of the experiment and after 3, 7, 14, 21, 28 and 35 days, and the cysteine desulphydrase (thionase) activity of the livers was measured in a Warburg apparatus. Thionase activity in rats on stock diet was at a maximum during the first 3 weeks after weaning. In rats having synthetic diets with added vitamin B₆ there was at first a decrease of thionase and then a progressive increase. In rats deprived of vitamin B₆ there was a marked decrease even after 3 days, and after 21 days the thionase activity was negligible. When the diet contained 40 per cent. of casein or extra methionine and cystine, the decrease was more rapid, and the animals showed signs of vitamin B₆ deficiency earlier than those having 20 per cent. of casein. If after 21 days' deprivation vitamin B₆ was given there was rapid restoration of thionase activity in the liver. It could be restored also *in vitro* by addition of pyridoxal phosphate to extracts of liver from deprived rats.

CALDWELL, E. F. and McHENRY, E. W. Vitamin B₆ and urea formation. *Arch. Biochem. Biophys.*, 1953, **44**, 396-403. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Urea formation was studied in tissue slices from livers of rats which had received for 6 weeks a

purified diet containing 20 per cent. of casein with or without pyridoxine. One group given pyridoxine had their food intake restricted to that of the group without pyridoxine. Deprivation of vitamin B₆ caused an increase in blood urea, and the livers from rats with high blood urea showed increased formation of urea *in vitro*. If the simple incubation medium with lactate and ammonia was supplemented with ornithine the increased urea formation in livers from rats deprived of vitamin B₆ was still greater.

In a further experiment a diet containing 5 per cent. casein was given for 25 days followed by the diet with 20 per cent. casein. The period of low-protein intake increased the effect of deprivation of vitamin B₆ on urea formation. Injection of alanine on the basis of 0.5 mg. alanine N per g. bodyweight depressed urea formation in liver slices within 12 hr., and caused the values for livers from rats with and without vitamin B₆ to be within nearly the same range.—A. M. Copping.

440

McFARLAND, W. Effect of high pyridoxine intake in cholesterol-fed chicks. *Arch. Pathol.*, 1953, **55**, 503-505. [Dept. Biochem., Pennsylvania State Coll., State College.]

In an experiment with 24 cockerels 5 weeks of age, a mash diet was supplemented with 1 per cent. of cholesterol, alone or with 16 or 80 mg. pyridoxine per lb. diet. The presence of pyridoxine did not reduce the blood cholesterol and when the birds were killed after 5 months the atherosclerotic lesions were more severe in those which had had pyridoxine than in those without.

441

RIGGS, T. R., COYNE, B. and CHRISTENSEN, H. N. Intensification of the cellular accumulation of amino acids by pyridoxal. *Biochim. biophys. Acta*, 1953, **11**, 303-304. [Dept. Biochem., Tufts Coll. Med. Sch., Boston, Mass.]

With cells of Ehrlich mouse-ascites carcinoma in Krebs Ringer bicarbonate solution, pyridoxal in appropriate concentration increased the amount of glycine accumulated from the medium by the cells by from 65 to 75 per cent. The effect appeared to depend on a definite concentration of pyridoxal in the extracellular fluid, since incubation of the cells in ascitic fluid with pyridoxal did not prevent subsequent stimulation when the ascitic fluid was replaced by pyridoxal in Krebs Ringer solution.

Pyridoxal phosphate was less effective than pyridoxal. No effect was given by pyridoxamine, pyridoxine, riboflavin, vitamin B₁, nicotinic or pantothenic acid.

The concentration by the cells of L- α -diaminobutyric acid also was stimulated by pyridoxal.

PANTOTHENIC ACID

442

SZALKOWSKI, C. R. and DAVIDSON, J. H. (Jr.) **Colorimetric determination of calcium pantothenate.** *Anal. Chem.*, 1953, **25**, 1192-1195. [Control Div., Merck and Co., Inc., Rahway, N.J.]

In vitamin mixtures, purification by chromatography on a Florisil tower, followed by treatment with cupric sulphate and calcium hydroxide, yielded a product in which calcium pantothenate could be estimated without interference. It was hydrolysed in acid, yielding $\alpha\gamma$ -dihydroxy- $\beta\beta$ -dimethylbutyric acid, which reacted with 2:7-naphthalenediol in sulphuric acid solution to give a coloured product with absorption at 465 m μ . from which it could be estimated.—R. Marshall.

LÉVY, G. and GIROUD, A. Dosage de l'acide pantothénique du foie d'embryon de rate. [Estimation of pantothenic acid in the liver of the embryo rat.] *Bull. Soc. Chim. biol.*, 1953, **35**, 507-510.

Livers were rapidly removed from the embryos of rats killed on the 21st day of gestation, and were frozen at -20°C . for immediate analysis or were lyophilised and stored until it was convenient to use them. The two methods gave almost identical results. Pantothenic acid was estimated microbiologically after liberation from the tissues by autolysis. The values found for the livers of all the embryos in a litter were similar and, for the 5 litters studied, little difference was found, the average values ranging from 22.1 to 34.4, with a mean of 27.5, m μg . per g. fresh liver.

NOVELLI, G. D. **Studies concerning the structure of coenzyme A.** *J. Cell. Comp. Physiol.*, 1953, **41**, Suppl. 1, 67-87. [Biochem. Res. Lab., Massachusetts Gen. Hosp., Boston.]

Work is described to determine the structure of co-enzyme A, and it is suggested that it consists of 1 mole each of pantothenate, adenine, ribose and β -mercaptoethylamine, and 3 of phosphate. In the suggested structure pantothenate is connected to adenosine through a pyrophosphate bridge and to β -mercaptoethylamine through the carboxyl group of the β -alanine portion of pantothenate. Reservations are made concerning the exact positions of the free phosphate group on the adenosine moiety, and of the attachment of the pyrophosphate bridge to pantothenic acid.

KLEIN, H. P. and LIPMANN, F. **The relationship of coenzyme A to lipide synthesis. 1. Experiments with yeast. 2. Experiments with rat liver.** *J. Biol. Chem.*, 1953, **203**, 95-99; 101-108. [Biochem. Res. Lab., Massachusetts Gen. Hosp., Boston.]

1. A strain of *Saccharomyces cerevisiae*, deprived of co-enzyme A by washing, was grown in the pantothenic-acid-deficient basal medium of Sarett and Cheldelin (Abst. 1370, Vol. 15) with vigorous aeration, or occasionally with small amounts of pantothenic acid. Normal co-enzyme A content was restored by the method of Novelli and Lipmann (*J. Biol. Chem.*, 1950, **182**, 213). Total lipids and steroids were estimated before and after incubation.

With increasing concentration of pantothenic acid in the medium, cell yield and sterol content per unit weight were functions of the initial concentration. There was also a parallel between the content of steroid (ergosterol) and of cellular co-enzyme A. Comparisons in aerobic conditions of lipid synthesis by resting yeasts poor or rich in co-enzyme A showed a close relationship between co-enzyme A content and the ability to synthesise lipids.

Low co-enzyme A content of yeast could be increased in anaerobic conditions by pantothenic acid in the presence of a high content of glucose. There was no increase in lipids, but when labelled acetate was supplied there were significant differences between cells poor and rich in co-enzyme A in their ability to incorporate acetate into fatty acids and steroids.

2. Male weanling albino rats received a basal diet with or without pantothenic acid. After from 4 to 6 weeks, the deprived animals showed signs of deficiency. The rats were then killed and liver slices were prepared and incubated with radioactive acetate in Ringer solution. Measurement was made of co-enzyme A and of labelled acetate in cholesterol and fatty acids. The respiration rate was estimated manometrically.

Livers deficient in co-enzyme A synthesised relatively little lipid. Livers occasionally retained large amounts of co-enzyme A and functioned almost normally although the rats showed typical outward signs of pantothenic acid deficiency. Values for fatty acids and cholesterol were low in the livers of animals lacking co-enzyme A. The content of co-enzyme A had little effect on respiratory rate. In the presence of pantooyltauryl-*p*-anisidide the synthesis of steroid and fatty acids by livers with a low content of co-enzyme A was

depressed; this effect was partially reversed by pantethine but not by pantothenic acid or coenzyme A.—V. R. Jackson.

chromic; in non-deficient hypertensive dogs the anaemia was microcytic and hypochromic.

ERSHOFF, B. H., SLATER, R. B. A. and GAINES, J. G. **Effects of pantothenic acid deficiency on pituitary-adrenal function in the rat.** *J. Nutrition*, 1953, **50**, 299-316. [Emory W. Thurston Labs., Los Angeles, Calif.]

Two groups of weanling rats were given a purified diet with or without pantothenic acid and a third group received the diet with pantothenic acid but in amounts restricted to the intake of the deprived rats. After 30 days, when some of the deprived rats had died and weight was stationary in all, blood counts were made on blood obtained from the tail immediately and 2, 4 and 24 hr. after injection of adrenaline or adrenocorticotrophic hormone. The lymphopenic response to the hormones was not impaired by lack of pantothenic acid. Measurement of ascorbic acid and of cholesterol in the adrenal glands of rats with and without pantothenic acid and treated with adrenaline or adrenocorticotrophic hormone showed no significant difference attributable to the deficiency. Intact rats deprived of pantothenic acid survived after injection of egg white which was highly lethal to adrenalectomised, non-deprived rats. It is concluded that no significant impairment of pituitary or adrenal function was associated with pantothenic acid deficiency.—A. M. Copping.

VITALE, J. J., HEGSTED, D. M., DIGIORGIO, J. and ZAMCHECK, N. **Interrelations between pantothenic acid, protein and calorie intakes with respect to respiration and morphology of duodenal mucosa.** *Metabolism*, 1953, **2**, 367-374. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Weanling albino rats received a purified basal diet with 18 per cent. casein or one with the casein raised to 60 per cent. at the expense of sucrose. B vitamins were added to each of the diets to provide, in mg. per 100 g. diet, nicotinic acid 4, riboflavin 0.8, pyridoxine HCl 0.4, vitamin B₁ 0.4, calcium pantothenate 2, or 5 times those amounts. Pantothenic acid deficiency was produced by omitting pantothenic acid from the diet, but to maintain a chronic deficiency for 90 days the basal diet with 2 mg. pantothenic acid per 100 g. was given on one day weekly. Some rats receiving the non-deficient diets were fed to appetite or restricted to 10 g. a day. When the rats were killed the respiratory rate of the duodenal mucosa was estimated manometrically.

Restricted intake of the non-deficient basal diet with 18 per cent. protein, but not of that with 60 per cent., reduced the O₂ consumption (QO₂) of the duodenal mucosa. In pantothenic-acid-deficient animals fed to appetite neither high protein nor high vitamin intake sufficed to maintain the normal QO₂. Bleeding into the small intestine occurred in all the pantothenic-acid-deficient rats, and the fall in the QO₂ occurred soon after occult blood was detected in the faeces.

The specific effect of pantothenic acid deficiency on the QO₂ could be shown only when the protein intake was normal or high, and the use of paired feeding and food restriction in such experiments is criticised.—V. R. Jackson.

LUECKE, R. W., HOEFER, J. A. and THORP, F. (Jr.) **The supplementary effects of calcium pantothenate and aureomycin in a low protein ration for weaning pigs.** *J. Animal Sci.*, 1953, **12**, 605-610. [Dept. Agric. Chem., Michigan Agric. Exp. Stat., East Lansing.]

Six groups of 10 weanling pigs were given a maize and soya bean meal diet alone or with a supplement of 5 mg. aureomycin, or 2 or 4 mg. Ca pantothenate per lb. diet, or combinations of aureomycin and pantothenate. Significant improvement in weight gain and feed utilisation was observed in all groups receiving pantothenate, and a supplement of 2 mg. appeared to be as satisfactory

N.A. and R., January 1954

as one of 4 mg. With aureomycin alone, weight gain was slightly superior to that on the basal diet, but half the pigs showed signs of pantothenic acid deficiency although the diet contained 4.15 mg. pantothenate per lb.; the addition of a further 2 mg. pantothenate protected. The problems of the requirement for pantothenate and of the physiological availability of pantothenate in the diet are discussed.—A. M. Copping.

451

FIDANZA, A., GIUNCHI, G., RUTIGLIANO, M. L., SCURO, L. A. and SORICE, F. Influenza di vari antibiotici sull'acrescimento di giovani ratti alimentati con dieta sintetica, priva di acido pantotenico. [Effect of various antibiotics on the growth of young rats fed on a

synthetic diet without pantothenic acid.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 69–71. [Ist. Fisiol., Univ. Rome.]

It was previously observed that chloramphenicol influenced favourably the growth of young rats deprived of pantothenic acid (Abst. 4299, Vol. 23). Six groups of from 7 to 9 young rats weighing from 30 to 60 g. were given a basal diet complete except for pantothenic acid, alone, or with aureomycin, penicillin, chloramphenicol, streptomycin or pantothenic acid. All the antibiotics raised the growth performance above that of the group having no addition. Aureomycin was the most effective, growth being about three-quarters of that with pantothenic acid; with the other three antibiotics growth was about half.

BIOTIN

452

TERROINE, T. Action de bleu de méthylène sur la vitesse d'apparition des symptômes caractéristiques de la carence en biotine. [Effect of methylene blue on the speed of appearance of the signs characteristic of biotin deficiency.] *C.R. Acad. Sci.*, 1953, **236**, 2265–2267.

Three groups of rats received a diet deficient in biotin, or the same with 5 times the amounts of vitamins B₁, B₆ and riboflavin adequate to prevent the signs of secondary deficiencies from appearing, or the same deficient diet with methylene blue.

There was no difference between the groups in appetite. Methylene blue and, to a less extent, the extra B vitamins delayed the development of signs which included alopecia, oedema and abnormal gait, but did not retard loss of weight. Methylene blue also prolonged survival time.

453

AXELROD, A. E. and HOFMANN, K. The failure of biotin or oxybiotin to exert a "procarcinogenic" effect on tumor formation by 4-dimethylaminoazobenzene. *Cancer Res.*, 1953, **13**, 442–444. [Inst. Pathol., W. Pennsylvania Hosp., Pittsburgh.]

Groups of 20 male weanling albino rats received a purified basal diet containing dimethylaminoazobenzene, alone or supplemented with 40 µg. *d*-biotin or 800 µg. *dl*-oxybiotin per 100 g. At death or after 8 or 12 months, the liver was removed for histological examination, and biotin and oxybiotin were estimated in both the liver and the tumour.

After 8 months, no hepatic tumour was present in any group and the degree of histopathological change was the same. After 12 months, those

receiving basal diet only showed signs of mild biotin deficiency and the biotin content of the liver was reduced. The number of animals surviving in the respective groups was 17, 17 and 15, with 2 in each group showing tumours. All those that died earlier had tumours. The incidence of tumour, either hepatoma or adenocarcinoma, and the degree of histopathological change, was the same in all the groups. The biotin content of the tumours was significantly less than of liver tissue, which remained normal. It is concluded that there is no evidence that biotin or oxybiotin promotes the carcinogenic effect of a diet containing 4-dimethylaminoazobenzene.—V. R. Jackson.

454

DI MARCO, A., ZANCHI, B. and ZAVAGLIO, V. Inibizione della crescita di M.TBC. da antagonisti di biotina. [Inhibition of growth of *Mycobacterium tuberculosis* by antagonists of biotin.] *Sperimentale*, 1952, **102**, 339–346. [Lab. Ric. Farmitalia, Milan.]

For *Mycobacterium tuberculosis*, *in vitro*, biotin in increasing concentration overcame the inhibitory effect in increasing concentration of the hydrazide of (4-imidazolidone-2)-caproic acid, which is structurally related to biotin.—E. M. Hume.

455

EVANS, R. J., DAVIDSON, J. A., BAUER, D. and BUTTS, H. A. The biotin content of fresh and stored shell eggs. *Poultry Sci.*, 1953, **32**, 680–683. [Dept. Agric. Chem., Michigan State Coll., East Lansing.]

Eggs from White Leghorn hens maintained on a ration of constant composition were tested for biotin after storage at 0° C. for 3, 7 or 12 months. The eggs were boiled for 30 min. before being

tested by the procedure of Wright and Skeggs (Abst. 2261, Vol. 14) with *Lactobacillus arabinosus* as test organism. Fresh shell eggs contained on an average 225 $\mu\text{g.}$ per g. or 10.76 $\mu\text{g.}$ per egg of which 2.25 $\mu\text{g.}$ was in the white and 8.52 $\mu\text{g.}$

in the yolk. The concentration in the white and yolk was 70 and 520 $\mu\text{g.}$ per g., respectively. No loss of biotin occurred in storage and there was no transfer of the vitamin between white and yolk.

p-AMINOBENZOIC ACID

456

SIRKS, J. L. **Derivatives of *p*-aminobenzoic acid and their action on the growth of bacteria.**

Non-competitive antagonists for derivatives of *p*-aminobenzoic acid. *Antonie van Leeuwenhoek J. Microbiol. Serol.*, 1953, **19**, 166-170; 171-180. [Bacteriol. Serol. Lab., Univ. Groningen.]

Derivatives of *p*-aminobenzoic acid obtained by substitution in the benzene ring were tested for their effect on the growth of *Aerobacter aerogenes* in synthetic medium and of *Diplococcus pneumoniae* in ascites broth without peptone. Growth was inhibited by the 2-amino-, 3-amino-, 3-dimethyl-, 3-hydroxy-, 2-chloro- and 2-bromo-derivatives, by the last 3 only in high concentrations. The 2-hydroxy-, 2-fluoro- and 2-nitro-derivatives caused slight growth stimulation. Other derivatives tested, including nitro- and acetamino-compounds, were inactive.

Further study of some of the derivatives which inhibited growth was made with *Bacterium coli* and showed that the inhibition could be overcome by *p*-aminobenzoic acid and by a number of other substances such as methionine, xanthine, serine, thymine and valine. The effect of these non-competitive antagonists varied for the various

derivatives, and a hypothesis is put forward to explain the results with the suggestion that the derivatives do not compete directly with *p*-aminobenzoic acid for an essential enzyme, but that they are used by the bacterium to form pteroylglutamic acid derivatives which may in turn compete for the enzyme.—A. M. Copping.

457

YAMAMOTO, T. and SUZUKI, K. **Effect of *p*-aminobenzoic acid and some antibiotics on rickettsial toxicity for mice.** *Jap. J. Exp. Med.*, 1952, **22**, 325-331. [Inst. Infect. Dis., Univ. Tokyo.]

The inhibitory effect of *p*-aminobenzoic acid, penicillin, chloramphenicol and aureomycin on the toxin of *Rickettsia mooseri* was tested by mixing them in different concentrations with toxin before it was injected into mice. If the mixtures were injected immediately, toxicity was not lessened, but if they were kept for 2 hr. or longer at 35° C. it was considerably decreased. Aureomycin was the most effective inhibitor and *p*-aminobenzoic acid the least. The results are discussed with reference to other reports of the effects of *p*-aminobenzoic acid and antibiotics in experimental and clinical rickettsial infections.—A. M. Copping.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

458

AVALOS BUSTAMANTE, B. **Estudio químico funcional y valoración fotocolorimétrica del ácido pteroilglutámico (fólico) en especialidades farmacéuticas. [Chemical properties and photocolorimetric estimation of pteroylglutamic (folic) acid in pharmaceutical preparations.]** *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 696-706. [Lab. Bioquim. Espec., Univ. Nac. Mayor de San Marcos, Lima.]

A colorimetric method was elaborated for estimating folic acid in acid medium by liberation of the *p*-aminobenzoic fraction and diazotisation of this substance. The method was found highly accurate for amounts of 0.25 to 5.0 mg. folic acid. In a number of preparations containing folic acid the amounts found ranged from 80 to 98.5 per cent. of the amounts stated to be present.

ANDREWS, M. M. and SCHWEIGERT, B. S. **Studies on the measurement of the folic acid and citrovorum factor potencies of certain natural products.** *Arch. Biochem. Biochys.*, 1953, **44**, 165-175. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

N.A. and R., January 1954

Folic acid was estimated with *Lactobacillus casei* and *Streptococcus faecalis* R, and citrovorum factor with *Leuconostoc citrovorum*, in yeast extract and beef liver, kidney, rib muscle, spleen and heart. The problem of the enzymic treatment in preparing samples was investigated; addition of cysteine increased the total folic acid measured in liver but not in other tissues or in yeast. The most effective method of liberating folic acid and citrovorum factor from bound forms varied with the tissue examined. Studies were made also of the stability of the two factors to heat treatment at pH 4 and pH 7 and in the presence of enzymes. Autoclaving at pH 7 for 5 min. in presence of cysteine gave fairly satisfactory results, and showed that for most tissues the greater portion of the total folic acid activity was due to folic acid and not to citrovorum factor, but for spleen and heart about 70 per cent. of the potency might be in the form of citrovorum factor.—A. M. Copping.

461

BOND, T. J. **Production of folinic acid from folic acid by *Lactobacillus casei*.** *Science*, 1953, **117**, 563-564. [Dept. Chem., Baylor Univ., Waco, Tex.]

When *Lactobacillus casei* was grown in a synthetic medium containing purines and folic acid, folinic acid was synthesised in amounts which increased with increasing concentration of folic acid. The folinic acid was measured with cultures of *Leuconostoc citrovorum*, which tended to become acid in spite of the presence of phosphate buffer so that some of the folinic acid may have been destroyed by acid hydrolysis before it could be estimated.

A. M. Copping.

462

NICHOL, C. A. **On the metabolic alteration of pteroylglutamic acid.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 167-170. [Dept. Pharmacol., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

Weanling albino rats and Rhode Island chicks were depleted of folic acid by diets containing succinylsulphathiazole. Preparations, involving autolysis for 18 hr. to produce citrovorum factor, were made from the tissues and incubated with *Leuconostoc citrovorum* for 18 hr. with or without pteroylglutamic acid. Growth was estimated turbidimetrically.

A small amount of citrovorum factor was formed by all tissues except blood but conversion of pteroylglutamic acid occurred mainly in the liver. The amount of citrovorum factor in bone marrow was small but the relative increase of it in the presence of pteroylglutamic acid was greater than in the other tissues except liver. In livers of rats depleted of folic acid, the amount of citrovorum factor increased within 1 hr. of an intra-

peritoneal injection of pteroylglutamic acid and fell after 24 hr. to that of normal animals.

Slices of liver from depleted rats or chicks were incubated under N₂ or O₂, and the yields of citrovorum factor were considerably higher in the anaerobic conditions. Addition of Na ascorbate increased the yield.—V. R. Jackson.

463

WOODS, D. D. **Folic acid and related compounds in the metabolism of micro-organisms.** *Brit. Med. Bull.*, 1953, **9**, 122-125. [Microbiol. Unit, Dept. Biochem., Univ. Oxford.]

464

RAUEN, H. M. and JAENICKE, L. Über "aktivierete Ameisensäure" und die fermentative Transformylierung. ["Activated formic acid" and enzymic formylation.] *Hoppe-Seyler's Ztschr.*, 1953, **293**, 46-47. [Physiol. Chem. Inst., Univ. Marburg a.d. Lahn.]

A preliminary report is given on studies of enzymic transfer of formyl groups in the synthesis and breakdown of formylfolic acid in liver homogenates from the sheep, pig, cow and calf. The integrity of the respiratory cycle of the tissue appeared to be essential, and adenosinetriphosphate catalysed the enzymic formylation. The most effective formyl donors were serine and histidine. With the demonstration of enzymic removal of the formyl group a theory of a trans-formylation cycle is suggested to include the so-called activated formic acid.—A. M. Copping.

465

TOTTER, J. R. **The biological functions of pteridine derivatives.** *J. Cell. Comp. Physiol.*, 1953, **41**, Suppl. 1, 241-259. [Univ. Arkansas Sch. Med., Little Rock.]

Work on the biological functions of pteridines is summarised and discussed, particularly the theory that pteroylglutamic acid or its co-enzyme acts as a transformylase. It is considered that undue emphasis has been placed in the past on the trans-formylating activity of pteridines and that other important functions have been overlooked. An alternative mechanism is suggested to explain failure of purine synthesis in folic acid deficiency and secondary related vitamin deficiencies. It is suggested that many signs of folic acid deficiency may be attributable to deficiencies of co-enzymes, especially co-enzyme A, caused by low tissue concentrations of adenylic acid.—V. R. Jackson.

SAUBERLICH, H. E. **Studies on the reversal of aminopterin toxicity in the rat with citrovorum factor, folacin and related compounds.** *J. Nutrition*, 1953, **50**, 101-115. [Dept.

Animal Husb., Alabama Agric. Exp. Stat., Auburn.]

Young rats receiving a purified diet containing 20 per cent. of casein with all vitamins of the B complex were given additional supplements of aminopterin, folic acid, synthetic citrovorum factor, penicillin, aureomycin, vitamin B₁₂, ascorbic acid and cortisone in various combinations. Aminopterin in an amount of 0.75 to 1.0 mg. per kg. in the diet was highly toxic but daily injection of 25 µg. citrovorum factor partly overcame the toxicity and inclusion of 100 µg. did so entirely. Injection of folic acid was ineffective but in the diet 100 mg. per kg. protected the rats. Citrovorum factor was effective by mouth as well as by injection and full protection was given by from 5 to 10 mg. per kg. diet. Injections of cortisone or ascorbic acid with or without folic acid gave no protection, but cortisone enhanced the effect of small injections of citrovorum factor. Antibiotics had no effect on the toxicity of aminopterin.

Studies were made of the enzyme systems in livers of rats given aminopterin, and disturbances of transmethylation were found with low methionine formation. The effect was overcome by adequate doses of citrovorum factor or folic acid.

The ascorbic acid content of the liver and adrenal glands was low in rats given aminopterin.

In one test increase in the protein content of the diet to 50 per cent. appeared to increase the toxic effect of aminopterin.—A. M. Copping.

467

GOLDIN, A., MANTEL, N., VENDITTI, J. M. and GREENHOUSE, S. W. **An analysis of dose-response for animals treated with aminopterin and citrovorum factor.** *J. Nat. Cancer Inst.*, 1953, **13**, 1463-1471. [Clin. Res. Unit, Nat. Cancer Inst., U.S. Pub. Health Serv. Hosp.]

In previous studies with mice, a linear relationship was observed between the doses of aminopterin and that of concomitantly administered citrovorum factor which together were predicted to kill 50 per cent. of the mice. As a result, an experiment was carried out with citrovorum factor and aminopterin given at different levels to 320 mice. The experiment was to test the hypothesis that these substances were competitively antagonistic.

The methods of this experiment are described in detail. The results are given, using probit analysis methods, along with similarly treated data from another series of experiments. Two tables and an appendix give the details of the method and 2 text figures illustrate the results obtained. Finally the results confirming the hypothesis are discussed with reference to "inhibition analysis" in the mammalian organism.

NICHOL, C. A., ZAKRZEWSKI, S. F. and WELCH, A. D. **Resistance to folic acid analogue in a strain of *Streptococcus faecalis*.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 272-277. [Dept. Pharmacol., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

The response of resistant and non-resistant strains of *Streptococcus faecalis* to aminopterin, amethopterin and other antagonistic analogues of folic acid was examined by a bio-autographic technique on paper strip chromatograms. Certain analogues supported growth in the resistant strain, and the method showed that they contained sufficient pteroylglutamic acid or pterioic acid to account for such an effect. The resistant strain appeared to have a low requirement for folic acid and a high capacity for converting folic acid into citrovorum factor, so that its growth was inhibited only by very high concentrations of antagonistic analogues.—A. M. Copping.

PHILLIPS, W. E. J., MAW, W. A. and COMMON, R. H. **Some effects of a folic acid antagonist on the responses of the immature pullet to treatment with gonadal hormones.** *Canad. J. Zool.*, 1953, **31**, 342-350. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

Pullets about 10 weeks old received a stock diet low in folic acid for a week and were then divided into 6 groups receiving no supplement or receiving oestradiol and testosterone on 5 alternate days, with or without aminopterin, or with feed intake restricted to that of birds receiving aminopterin. The birds were killed 2 days after the last hormone injection.

Hypertrophy of the oviduct caused by hormones was progressively decreased by aminopterin up to 0.5 mg. daily. There was no significant effect on liver pentose or deoxypentose nucleic acids. The hormones increased, and aminopterin did not affect, liver phosphoprotein or serum Ca. Folic acid, but not Na deoxyribonucleic acid, antagonised the effect of aminopterin in depressing oviduct response, and folic acid with aminopterin significantly decreased serum Ca. Deoxyribonucleic acid appeared to counteract the depressant effect of aminopterin on the weight of the spleen and adrenal glands.—V. R. Jackson.

VITAMIN B₁₂

471

JOHANSSON, K. R. **Response to and assay of vitamin B₁₂ by a mutant of *Escherichia coli*.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 448-453. [Dept. Bacteriol., Univ. Minnesota, Minneapolis.]

The mutant strain, *Bacterium coli* 113-3, was used to estimate vitamin B₁₂ with turbidity as criterion of response. The response varied with degree of aeration, growth being suppressed in anaerobic cultures. The organism responded to vitamin B₁₂ and to methionine in a medium containing mineral salts, citrate and glucose. Vitamin B_{12a} showed about 70 per cent. of the activity of vitamin B₁₂ in the test. When cyanide was present in the medium, vitamin B_{12a} was apparently converted into a substance with activity equivalent to vitamin B₁₂. Cyanide, or ascorbic acid or sodium thioglycollate in high concentrations, apparently destroyed the growth-stimulating property of vitamins B₁₂ and B_{12a}. In lower concentrations, cyanide and thioglycollate had some effect in protecting the vitamins against heat. Use of *Bact. coli* 113-3 is claimed to offer a simpler procedure for estimating vitamin B₁₂ than use of *Lactobacillus* species.—A. M. Copping.

TAUB, A. and LIEBERMAN, H. **Stability of vitamin B₁₂—folic acid parenteral solutions.** *J. Amer. Pharm. Assoc.*, 1953, **42**, 183-186. [Coll. Pharm., Columbia Univ., New York.]

Solutions suitable for injections could be prepared at a concentration of 30 µg. vitamin B₁₂ and 5 mg. folic acid per ml. at a pH of 6 and up to 6.5 in the presence of 10 per cent. nicotinamide. They were sufficiently stable, in respect of clarity of solution and potency of folic acid and vitamin B₁₂, to be useful in practice.—K. H. Coward.

BAXTER, N., HORSFORD, J., WOKES, F., NORRIS, F. W. and FERNANDES, S. J. G. **Cyanocobalamin and hydroxocobalamin in vitamin B₁₂ injections.** *J. Pharm.*, 1953, **5**, 723-736. [Ovaltine Res. Labs., King's Langley, Herts.]

A study of 66 different batches from several sources of vitamin B₁₂ for injection showed that they contained considerable proportions of hydroxocobalamin, sometimes involving as much as half of the cobalamin present. A spectrophotometric method of estimating cyanocobalamin in the presence of varying amounts of hydroxocobalamin was developed and checked by microbiological estimations on 11 samples of vitamin B₁₂ solutions before and after destruction of hydroxocobalamin

with ascorbic acid. Most of the 66 batches had a cyanocobalamin content between 90 and 110 per cent. of that claimed. In those with a content below the claim, the deficit was probably due to conversion of cyanocobalamin to hydroxocobalamin under the action of light; reconversion to cyanocobalamin could be effected by storage in the dark.—K. H. Coward.

474

ERICSON, L. E. **Note on vitamin B_{12b}.** *Acta chem. scand.*, 1953, **7**, 703-704. [Div. Food Chem., Royal Inst. Technol., Stockholm.]

Ionophoresis of vitamin B_{12b} from *Streptomyces aureofaciens* on paper in an acetate buffer indicated the presence of 8 substances, all active as growth factors for *Bacterium coli* 113-6. One of the main components appeared to correspond with the major component of factor A described by Holdsworth (Abst. 2958, Vol. 23). Another appeared to be pseudovitamin B₁₂. Four of the components moved towards the anode, of which one was probably vitamin B_{12s}. A yellow compound also was observed. The probable identity of the various components is discussed.

PAOLINO, W. and PINNA-PINTOR, P. **Diversità di azione tra vitamina B₁₂ ed acido folico nei riguardi della evoluzione maturativa dei reticulociti. Azione maturante della vitamina B₁₂. [Difference in the action of vitamin B₁₂ and folic acid on the maturation of the reticulocytes. Maturing action of vitamin B₁₂.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 207-210. [Ist. Patol., Univ. Turin.]
Red cells and reticulocytes were counted every 12 hr. on the day before, and up to 204 hr. after, withdrawal of about one-third of the total amount of blood from 5 rabbits of which 4 were injected with 15 µg. vitamin B₁₂ 36, 60, 84, 108 and 132 hr. after blood letting. The red cell count did not differ significantly among the 5 animals, but the reticulocyte response was less and subnormal in those given vitamin B₁₂. Folic acid given in the same way was without effect on the blood picture. The effect produced by vitamin B₁₂ is considered to have been due to accelerated maturation of the reticulocytes and not to inhibition of haemopoiesis.—E. M. Hume.

SARACCHI, F. **Ricerche polarografiche sull'eliminazione renale del cobalto somministrato come cloruro e come vitamina B₁₂. [Polarographic studies of renal excretion of cobalt given as the chloride and as vitamin B₁₂.]** *Arch. Sci. biol., Bologna*, 1953, **37**, 221-228. [Ist. Farmacol., Univ. Pavia.]
For 10 days Co was estimated polarographically in the urine of rats given a single subcutaneous injection of 2.5 mg. Co per kg. bodyweight as chloride or as vitamin B₁₂. In 2 rats given chloride, elimination was greatest on the day after injection and was still considerable on the second day. It then decreased sharply and by the ninth day had ceased. The total excreted, as a percentage of that given, was 70 and 72, respectively, for the 2 rats. In the 2 rats given vitamin B₁₂, the amount eliminated was greatest on the first day, but was still relatively large up to the sixth day; elimination ceased by the ninth day. The total percentage found in the urine was 43 and 45.—E. M. Hume.

JACKSON, J. T., MACHLIN, L. J., BRANDENBURGER, E. A., KELLOGG, W. L. and DENTON, C. A. **Retention of Co 60 labeled vitamin B₁₂ in chickens.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 221-222. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]
The vitamin B₁₂ content of whole chicks and their excreta was measured 1 day and 3, 6, 9 and 12 weeks after hatching from eggs which had been injected with 3 µg. of vitamin B₁₂ on the sixth day of incubation. In one group the vitamin B₁₂ contained ⁶⁰Co, in another the vitamin was unlabelled, and in the third no vitamin B₁₂ was given. Up to 6 weeks of age the total vitamin B₁₂ recovered accounted for the radio-activity measured in the body and excreta, and only subsequently was there an increase in the vitamin B₁₂ content of the chick from diet or from intestinal synthesis. After 12 weeks, over 30 per cent. of the injected vitamin B₁₂ was still present as shown by the ⁶⁰Co activity in the body. The chicks hatched from eggs injected with vitamin B₁₂ showed the improved growth response previously reported by Lillie *et al.* (Abst. 413, Vol. 20).—A. M. Copping.

LANG, C. A., GLEYSTEN, D. M. and CHOW, B. F. **The disappearance of radioactivity from the tissues of rats of different ages after subcutaneous administration of radiovitamin B₁₂.** *J. Nutrition*, 1953, **50**, 213-222. [Dept. Biochem., Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.]
Vitamin B₁₂ containing ⁶⁰Co was injected into young rats aged from 2 to 3 months and old rats of the same stock aged from 14 to 18 months. Urine was collected for 48 hr.; some animals were then killed and others were killed 14 days after the injection. The distribution of radio-active

vitamin B₁₂ in the urine, liver and kidneys was the same in young and old animals after 48 hr. but after 14 days the old rats showed a greater amount of radio-activity in the kidney but not in the liver.

CHARKEY, L. W., MANNING, W. K., KANO, A. K., GASSNER, F. X., HOPWOOD, M. L. and MADSEN, I. L. **A further study of vitamin B₁₂ in relation to amino acid metabolism in the chick.** *Poultry Sci.*, 1953, **32**, 630-642. [Dept. Chem., Colorado Agric. and Mech. Coll., Fort Collins.]

Day-old chicks of both sexes from hens depleted of vitamin B₁₂ were given basal diets low in the vitamin, with soya bean protein or groundnut cake as source of amino-acids, and with or without a supplement of vitamin B₁₂. All birds were fasted for 48 hr. during the 4th week of the experiment to ascertain the effect of increasing the demand of the tissues for amino-acids. The thyroid glands and gonads were weighed to find whether vitamin B₁₂ exerted its influence through them or not. Lysine, methionine, arginine, tryptophan and histidine were estimated microbiologically.

On the diet containing soya bean protein, growth, utilisation of feed and response to vitamin B₁₂ were greater than on the diet containing groundnut meal. The amino-acid content of the blood reflected the dietary intake of amino-acids, and the effect was discernible even after fasting, particularly with arginine and methionine. Vitamin B₁₂ increased the blood value for arginine and methionine, but had no effect on that for lysine, tryptophan and histidine; the effect was independent of the diet given. In the conditions of the experiment the effect of vitamin B₁₂ was not greater after fasting than before. Irrespective of previous diet, fasting reduced the blood values for arginine, methionine, tryptophan and histidine, but appreciably increased that for lysine. Lysine regained its original value within 4 hr. after food was given, and the values for the other amino-acids were higher than in the pre-fasting period.

None of the criteria associated with sex showed any difference dependent on the presence of vitamin B₁₂. The weight of the gonads and thyroid glands relative to bodyweight was reduced by fasting; total blood solids and thyroid iodine increased.—E. M. Cruickshank.

STEKOL, J. A., HSU, P. T., WEISS, S. and SMITH, P. **Labile methyl group and its synthesis de novo in relation to growth in chicks.** *J. Biol. Chem.*, 1953, **203**, 763-773. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Pullets, 3 days old, in groups of 6 to 10, received

Vol. 24, No. 1

a basal diet deficient in choline and methionine, containing, per cent., soya bean protein 23, maize starch 61.7, salt mixture 6, maize oil 5, succinylsulphathiazole 1.0, L-cystine 0.3, glycine 1.0 and agar 2, with added vitamins except vitamin B₁₂. Groups of them received supplements of homocystine, dimethylethanolamine, betaine and vitamin B₁₂, singly or in combination, for 5 weeks, after which each received a single intraperitoneal injection of radio-active methionine-CH₃-¹⁴C, choline-CH₃-¹⁴C, or betaine-CH₃-¹⁴C, and was killed 20 hr. later.

With all the diets addition of vitamin B₁₂ increased the rate of growth. Homocystine and dimethylethanolamine enhanced the effect of vitamin B₁₂. The best growth was obtained with all 4 supplements together, but homocystine, dimethylethanolamine and betaine without vitamin B₁₂ gave good growth. No perosis was seen in any bird which received dimethylethanolamine, but all other groups showed some degree of perosis, which was not correlated with rate of growth.

Isolation of radio-active choline, creatine and creatinine from the carcasses indicated that transfer of ¹⁴C from methyl groups of methionine or betaine to choline or creatine, or from choline to creatine, was not dependent on dietary vitamin B₁₂. ¹⁴C was incorporated into creatine from choline less efficiently than from methionine or betaine. Addition of homocystine to the basal diet increased transfer of ¹⁴C from choline and betaine to creatine. Synthesis of the labile methyl group in the absence of dietary methionine and choline is thought to be adequate provided that homocystine with vitamin B₁₂ or betaine is present.

ARNSTEIN, H. R. V. and NEUBERGER, A. **The effect of cobalamin on the quantitative utilization of serine, glycine and formate for the synthesis of choline and methyl groups of methionine.** *Biochem. J.*, 1953, **55**, 259-271. [Nat. Inst. Med. Res., Mill Hill, London.]

The synthesis of methionine and choline from [α -¹⁴C]glycine, [β -¹⁴C]serine or [¹⁴C]formate was studied in prolonged experiments with rats receiving basal diets containing mixtures of amino-acids with or without addition of vitamin B₁₂. In all the tests the radio-activity of the methyl groups in methionine exceeded that of the methyl groups in choline, suggesting that the new synthesis of methyl groups was primarily for incorporation into methionine with later transference to choline by transmethylation. When radio-active serine was given with vitamin B₁₂ in diets lacking preformed methyl groups, 70 per cent. of the radio-activity was found in the methionine of the viscera. Glycine was relatively inefficient as a methyl precursor and formate was efficient although it

was not readily converted to the hydroxymethyl group of serine. The presence of vitamin B₁₂ stimulated the synthesis of methyl groups from all three sources and the effect was found also in rats pair-fed with those deprived of the vitamin.

BEST, C. H., LUCAS, C. C., PATTERSON, J. M. and RIDOUT, J. H. **Some effects of vitamin B₁₂ in weanling rats consuming hypolipotropic diets.** *Canad. J. Med. Sci.*, 1953, **31**, 135-145. [Banting and Best Dept. Med. Res., Univ. Toronto, Ont.]

In an investigation of the protective effect of vitamin B₁₂ against haemorrhagic kidney lesions in very young rats having a diet lacking in choline, it was found that protection occurred only when methionine was present in the diet, and the requirement for methionine remained even when subprotective amounts of choline were present. Homocystine could not replace methionine. The effects were demonstrable only in weanling rats and under closely defined conditions. The problems involved in the processes of synthesising labile methyl groups and in the transfer of such groups are discussed with reference to hypolipotropic diets.—A. M. Copping.

489

KRATZER, F. H. **The relation of vitamin B₁₂ to the methylation of homocystine in poults.** *J. Biol. Chem.*, 1953, **203**, 367-371. [Dept. Poultry Husbandry, Coll. Agric., Univ. California, Davis.]

A diet almost completely devoid of methionine was given to turkey poults from hens receiving diets lacking animal protein and vitamin B₁₂. Addition of methionine to the diet improved growth, but homocystine gave only poor growth. A combination of homocystine and vitamin B₁₂ or betaine was more successful, and good results were obtained with the three together. When betaine was given without vitamin B₁₂ growth was fair but mortality was high. It is concluded that the turkey poult could methylate homocystine in presence of vitamin B₁₂ or of a methyl donor such as betaine in absence of the vitamin.

A. M. Copping.

490

ANDERSON, E. I. and STEKOL, J. A. **Vitamin B₁₂ and folic acid in the biosynthesis of component amino acids of glutathione.** *J. Biol. Chem.*, 1953, **202**, 611-618. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Rats 2 to 2½ months old were given stock diet, complete synthetic diet, or diets lacking in vitamin B₁₂ or folic acid, for at least 3 months before radio-active glycine or L-cysteine was injected. The

rats were killed one hour after the injection and the glutathione content of the livers was estimated. The radio-activity of the isolated glutathione was then measured. Although deprivation of vitamin B₁₂ or folic acid caused an apparent reduction of the glutathione content of the liver, the amount of radio-active glycine or L-cysteine incorporated into the glutathione was about the same in rats on complete and deficient diets. In rats deprived of vitamin B₁₂ or folic acid less carbon of glycine-2-¹⁴C was incorporated into the cysteine and glutamic acid portions of the liver glutathione. It is suggested that although vitamin B₁₂ and folic acid are probably not involved directly in the synthesis of glutathione, both may be involved in the conversion of glycine-2-¹⁴C to cysteine and glutamic acid.—A. M. Copping.

WILLIAMS, J. N. (Jr.), MONSON, W. J., HARPER, A. E. and ELVEHJEM, C. A. **Further studies on the relationship of vitamin B₁₂ to enzymes in rat liver.** *J. Biol. Chem.*, 1953, **202**, 607-610. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Weanling male rats were given a basal soya bean meal diet with or without a supplement of 2 µg. vitamin B₁₂ per 100 g. diet. After 5 weeks there was a difference of about 40 g. between the average bodyweights of the 2 groups, and the xanthine oxidase and transmethylese activities were less in the livers of those deprived of vitamin B₁₂. Injections of 2 µg. vitamin B₁₂ were then given to all the rats and enzyme activities were estimated in the livers from rats killed after 24 hr. or 4 or 8 days. The xanthine oxidase activity was only gradually restored but the betaine-homocysteine transmethylese system was restored within 24 hr. It was concluded that vitamin B₁₂ may act as a co-factor in the transmethylese system but its effect on xanthine oxidase is probably indirect and exercised through changes in general protein metabolism.—A. M. Copping.

492

ROLAND, J. F. (Jr.), MILLMAN, I. and GIFFEE, J. W. (Jr.) (with SIPOS, E.). **Fractional electrical transport studies of vitamin B₁₂ binding by proteins.** *J. Biol. Chem.*, 1953, **202**, 857-863. [Dept. Biochem. Res., Armour Labs., Armour and Co., Chicago, Ill.]

The method of Bird and Hoevet (Abst. 1850, Vol. 21) was used to measure the ability to bind vitamin B₁₂ of protein components separated from pig duodenal preparations by iso-electric fractionation by electrical transport in an apparatus similar to that described by Spies *et al.* (*J. Amer. Chem. Soc.*, 1940, **62**, 1420). The component of pig duodenal preparations responsible for the

N.A. and R., January 1954

greatest part of the vitamin-B₁₂-binding activity was acidic; the iso-electric point was at pH 4.6 and was not altered by combination with vitamin B₁₂. The ability of preparations from plasma and stomach of pigs to bind vitamin B₁₂ was investigated, and that from the plasma was the less active in similar conditions.—A. M. Copping.

BECK, E. M. and RALLI, E. P. **Influence of dietary factors and the adrenal on hyaluronidase spreading reaction in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 588-591. [Dept. Med., Coll. Med., Univ. New York.]

The intradermal spread of injected hyaluronidase was decreased in rats given large amounts of vitamin B₁₂ in the diet. It was not affected by excess or deficiency of pantothenic acid. The area of spread was decreased in adrenalectomised rats and in intact rats given cortisone. Sham operation without removal of the adrenal glands also decreased the area of spread. It is, therefore, suggested that the effect of adrenalectomy is non-specific and related to the operative procedure.

VAN KLAVEREN, F. W. and SHRIVASTAVA, P. C. **The lead anaemia in the rabbit and the potency of liver extracts.** *Indian J. Med. Res.*, 1952, **40**, 495-504. [Res. Lab., Teddington Chemical Factory, Ltd., Andheri, Bombay.]

Injection of 4 to 6 mg. lead acetate per kg. body-weight for 2 or 3 days produced severe anaemia in rabbits. If whole liver extract was injected in small doses at the same time as the lead acetate, the decrease in red blood cells and in Hb was checked and the effect appeared to be related to the vitamin B₁₂ content of the liver extract. In a further test which included 2 animals given crystalline vitamin B₁₂, the protective effect of a liver extract was greater than could be explained by its vitamin B₁₂ content. A purified liver fraction containing no vitamin B₁₂ produced a rise in red cell count when it was given with lead acetate.—A. M. Copping.

DANIEL, L. J. and GRAY, L. F. **Molybdenum toxicity in *Lactobacillus leichmannii*.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 487-490. [Dept. Biochem. Nutrit., Cornell Univ., Ithaca, N.Y.]

With large amounts of molybdenum, 40 to 80 mg. per 10 ml. medium, the growth of *Lactobacillus leichmannii* was inhibited, but the inhibition was rapidly overcome by relatively small doses of vitamin B₁₂. Co alone did not have the effect of vitamin B₁₂. Addition of cysteine, glutathione or BAL to the medium decreased the inhibition caused by Mo, owing, it is suggested, to formation of Mo mercaptides. The action of vitamin B₁₂ was less easily explained unless it was concerned in maintaining a reduced state in sulphhydryl enzymes or in maintaining or producing phosphate bonds.

FERRIOT, A., QUENTIN, J. and ROBERT, J. **Vitamine B₁₂ et antibiotiques dans la nutrition animale. 2. Essai dans l'élevage du porc. [Vitamin B₁₂ and antibiotics in the nutrition of animals. 2. Test in pig rearing.]** *Rec. Méd. vét.*, 1953, **129**, 226-238.

A test was made of the value of supplements of vitamin B₁₂ and aureomycin or other antibiotic in commercial pig rearing with diets based on by-products of the dairy industry, including whey and skimmed milk. The pigs given the supplements showed a higher rate of growth with a relatively lower feed consumption. The use of antibiotics improved the general condition of the pigs and prevented diarrhoea and other troubles. The meat produced by the supplemented diets was of high quality as pork and ham.

HUANG, T. C., SCHNEIDER, B. H. and COLBY, R. W. **Alfalfa, soil, vitamin B₁₂ and antibiotics in the nutrition of young pigs.** *Arch. Biochem. Biophys.*, 1953, **45**, 254-259. [Dept. Animal Husb., State Coll. Washington, Pullman.]

Weanling pigs were given basal diets containing 57.6 per cent. sucrose and 26.2 per cent. vitamin-free casein or α-protein, with vitamin and mineral supplements except vitamin B₁₂. Addition of 10 per cent. alfalfa meal did not improve growth or feed utilisation during a 5-week test but over 13 weeks it did. Alfalfa and vitamin B₁₂ together were more effective than alfalfa alone. Palouse silt loam topsoil improved growth and feed utilisation when it was added to the diet at the rate of 5 per cent. but not of 1 or 3 per cent. Previous incubation of the soil with chopped straw and

cobalt carbonate increased its growth-promoting effect. A supplement of 33 mg. terramycin per kg. diet was effective in improving the diet containing α-protein. Vitamin B₁₂ alone had little effect on growth and feed utilisation. The growth and feed utilisation of pigs kept in cages to prevent coprophagy were poorer than of pigs on a concrete floor and given the same diet.—A. M. Copping.

503

BALDINI, J. T., ROBERTS, R. E. and KIRKPATRICK, C. M. **Antibiotic and vitamin B₁₂ supplements as related to the crude protein level of bobwhite quail diets.** *Poultry Sci.*, 1953, **32**, 563-567. [Dept. Poultry Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

When quail were given a vegetable diet containing 20 per cent. protein, a supplement of condensed fish solubles improved growth and survival. When the fish solubles were combined with an antibiotic and vitamin B₁₂, growth was further increased and was equal to that when the diet contained 28 per cent. protein without any supplement. When the dietary protein was 24 or 28 per cent. the supplements alone or combined had no beneficial effect. The addition of an antibiotic and vitamin B₁₂ increased the efficiency of utilisation of feed and of protein, particularly when the dietary protein was only 20 per cent.

HANSEN, M. F., NORRIS, M. G. and ACKERT, J. E. **The influence of an all plant protein diet supplemented with aureomycin and vitamin B₁₂ on the resistance of chicks to *Ascaridia galli* (Schränk).** *Poultry Sci.*, 1953, **32**, 612-617. [Dept. Zool., Kansas State Coll., Manhattan.]

Chicks given an adequate vegetable ration with or without 0.9 mg. aureomycin and 0.9 mg. vitamin B₁₂ per 100 lb. feed were left untreated or given by mouth 100 ± 10 embryonated ova of *Ascaridia*. The mortality and the percentage of birds infected were less in those receiving the supplement. There was no significant difference in liveweight increase between infected and non-infected birds when they received the basal diet, but when the diet was supplemented parasitism had a detrimental effect on weight gain. The worm burden was heavier in chicks receiving the basal ration alone.

DANIEL, L. J., GARDINER, M. and OTTEY, L. J. **Effect of vitamin B₁₂ in the diet of the rat on the vitamin B₁₂ contents of milk and livers of young.** *J. Nutrition*, 1953, **50**, 275-289. [Dept. Biochem., Cornell Univ., Ithaca, N.Y.]

Young rats, from females which from 12 weeks of age had received a stock diet or a basal diet including 60 per cent. soya bean oilmeal and 1 per cent. succinylsulphathiozole, without vitamin B₁₂, or with 0.2 µg. or 20 µg. vitamin B₁₂ per 100 g. diet, were killed at 2 or 22 days of age. The curds in the stomach and the livers were tested for vitamin B₁₂ with *Lactobacillus leichmannii*. Even at 2 days of age the amount of vitamin B₁₂ in the livers was related to the amount in the maternal diet, which was taken to indicate that vitamin B₁₂ was transferred from mother to foetus in prenatal life. The vitamin B₁₂ content of the milk varied also with the maternal diet and was greater after 2 days than at the end of lactation. In young killed at 22 days of age vitamin B₁₂ in the liver had increased over the values found for littermates 2 days old except in the young of mothers given the unsupplemented diet, which showed a decrease in liver stores of vitamin B₁₂. Birthweights and weaning weights were related to the vitamin B₁₂ content of the diet but even with 20 µg. vitamin B₁₂ per 100 g. diet the weaning weights were not equal to those obtained on stock diet.

Second and third litters were obtained from some of the females on the purified diets but the reproductive performance was poor after the first litter. Those which achieved 3 lactations were killed and vitamin B₁₂ was measured in their livers. There was significantly less in rats given no vitamin B₁₂ than in those given a supplement, but even with 20 µg. per 100 g. diet there was less in the liver than in the liver of animals given the stock diet.—A. M. Copping.

507

HALICK, J. V., REID, B. L., BROWN, C. L. and COUCH, J. R. **The vitamin B₁₂ content of egg yolks as influenced by oral and parenteral administration of the vitamin.** *J. Nutrition*, 1953, **50**, 331-340. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

In 4 series of tests with white Leghorn pullets, the effect was studied of intramuscular injection of a daily dose of 250 µg. vitamin B₁₂, direct oral administration of the same dose, or inclusion of 1750 µg. per kg. in the diet. The highest increase in the vitamin B₁₂ content of the egg yolk occurred

when the vitamin was injected. There appeared to be considerable loss or destruction of it when ingested. Addition to the diet of a surface-active agent, a polyoxylene oxide-substituted amine, enhanced the absorption of vitamin B₁₂ and increased the amount appearing in the egg yolk. Eggs containing large amounts of vitamin B₁₂ hatched normally, and the chicks had much greater stores of vitamin B₁₂ in the liver than chicks from eggs with a normal vitamin B₁₂ content. The addition of the surface-active agent to the diet did not affect hatching capacity.

SOUTHCOTT, B. A. and TARR, H. L. A. **Vitamin B₁₂ in marine invertebrates and seaweeds.** *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1953, No. 95, 45-47. [Pacific Fish. Exp. Stat., Nanaimo, B.C.]

By paper chromatography and bio-autography it was shown that an acid extract of the clam, *Saxidomus giganteus*, contained some true vitamin B₁₂ as well as other active components related to it. Extracts from seaweeds, collected before the season of most vigorous growth, contained small amounts of vitamin B₁₂.—A. M. Copping.

510

BÄNHIDI, Z. G. and ERICSON, L. E. **Bioautographic separation of vitamin B₁₂ and various forms of folic acid occurring in some brown and red seaweeds.** *Acta chem. scand.*, 1953, **7**, 713-720. [Div. Food Chem., Royal Inst. Technol., Stockholm.]

Further studies were made of the growth factors in seaweeds (Abst. 4384, Vol. 23) by chromatographic and bio-autographic methods. Of the 6 algae tested none appeared to contain vitamin B₁₂, but *Laminaria saccharina*, *Polysiphonia nigrescens* and *Rhodomela subfusca* contained vitamin B_{12b}.

Several deoxyribosides were detected in all 6 algae. In all except *Rhodomela subfusca* a citrovorum factor resembling formyltetrahydrofolic acid was identified. Several slowly moving spots were observed in the chromatograms, and similar products were obtained from a yeast extract but not from a horse liver extract.—A. M. Copping.

OTHER B VITAMINS

511

TAPPAN, D. V., BOLDT, R. E. and ELVEHJEM, C. A. **Unidentified factors capable of reducing stress in iodinated protein-fed rats.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 135-139. [Dept. Biochem., Univ. Wisconsin, Madison.]

Male weanling albino rats received a basal diet containing casein 20 to 24, cystine 0.3, salt mixture 4, maize oil 5 and iodinated casein (Protamone) 0.15 to 0.5, with sucrose to 100, supplemented by adequate vitamins including 0.1 mg. vitamin B₁₂ per kg. Other groups received the diet with natural materials replacing equivalent amounts of casein, cystine and maize oil so that the levels of protein and fat were kept the same as in the basal diet.

In diets with 0.4 to 0.5 per cent. Protamone, survival was significantly prolonged by including in the diet pork protein, the antithyrototoxic activity of which was not removed by extraction with

ether and then water. A mixture of maize and soya bean replacing all the non-iodinated casein and sucrose of the basal diet gave even greater protection. Other active materials included muscle from other mammals, alfalfa leaf meal, yeast and whole liver. Dried egg and dried haddock, whole wheat, milk powder, crude casein, maize or soya bean meal as 20 per cent. of the diet, liver concentrates or cellulose had only slight protective activity.

Animals receiving the basal diet unmodified showed atrophy of the thymus and seminal vesicles and enlargement of the kidneys and adrenal glands, disorders which were reduced by the more protective materials, though, in the case of the adrenal glands, only if the Protamone content of the diet was low. The spleen was larger in the animals receiving protective materials

BALAKHOVSKII, S. D., DROZDOVA, N. N. and FEDOROVA, V. N. **O vliyanii karotina na okislenie askorbinovoi kisloty v prisutstvii medi.** [The effect of carotene on the oxidation of ascorbic acid in presence of copper.] *Biokhimiya*, 1953, **18**, 112-119. [Inst. Biochim. Im. A.N. Bakh., Akad. Nauk SSSR, Moscow.]

It has been shown experimentally that colloidal aqueous solutions of carotene can inhibit the catalytic oxidation of ascorbic acid in the presence of Cu. The inhibition cannot be explained by competition for oxygen. The carotene exerts this negative catalytic effect only when it is in a particular state of subdivision, and a method is described for preparing carotene solutions which retain their vitamin activity after several months' storage. In the experimental conditions the oxidation of carotene in aqueous media was not accelerated by Cu. A mixture of ascorbic acid and Cu stabilised colloidal aqueous solutions of carotene to a slight extent.—W. Hughes.

- PERSSON, B. H. **Studies on connective tissue ground substance. 1. Histochemical features of ground substance mucopolysaccharides. 2. Organization of the ground substance in ascorbic acid deficiency and its modification by the action of cortisone.** *Acta Soc. Med. upsalien.*, 1953, **58**, Suppl. 2, 1-104. [Dept. Histol., Univ. Uppsala, Sweden.]

1. The first part of the paper is concerned with a study of the metachromatic potency of purified samples of hyaluronic acid and chondroitin sulphuric acid, of commercial heparin and of some native samples of vitreous humour and synovial fluid. The metachromatic potency of hyaluronic acid depends on its state of polymerisation and is affected by the purity of the histochemical dyes used. Failure to take this into account may explain some of the differences between findings recorded in the literature.

2. The effect of ascorbic acid deficiency and of cortisone on the organisation of the connective tissue ground substance in growing female guineapigs was studied with the aid of these and other tests. In scurvy an increased amount of ground substance mucopolysaccharides was found, the hexosamine in the skin being increased significantly in comparison with normal animals. The ground substance complex was present in an abnormal

state, with high solubility in water, and increased permeability to penetrating agents. The water-binding capacity of the skin was increased also. In healing wounds, water-soluble ground substance was found in the granulation tissue. It did not show any metachromatic potency but reacted with Hale's colloidal iron, and with Schiff's leucofuchsin after oxidation with periodic acid. Removal of the adrenal glands aggravated the signs of scurvy and treatment of the scorbutic animal with cortisone tended to reverse the above findings.

W. Godden.

WU, M. C. C. and SEALOCK, R. R. **Factors concerned in tyrosine metabolism.** *Arch. Biochem. Biophys.*, 1953, **44**, 312-319. [Dept. Chem., Iowa State Coll., Ames.]

Male guineapigs received a commercial chow diet in which vitamin C had been destroyed by exposure to air. In a first experiment, after 3 days on the diet, the animals received a supplement of 200 mg. L-tyrosine per 100 g. bodyweight daily, with 0.9 g. brewer's yeast. Urine samples were analysed daily; when keto-acid excretion represented at least 30 per cent. of the extra tyrosine, single or repeated intraperitoneal injections of from 20 to 30 μ g. vitamin B₁₂ were given; they reduced the excretion of tyrosine metabolites, but smaller doses were ineffective.

In a second experiment the duration of vitamin C deprivation before the administration of tyrosine was varied from one to 14 days. The effect of vitamin B₁₂ decreased with increasing vitamin C deficiency and after 10 days was reversed, so that keto-acid excretion increased after vitamin B₁₂ injection. There was no clear correlation between vitamin C concentration in the tissues and vitamin B₁₂ effect, though a high concentration of vitamin C in the liver and kidneys seemed to favour the effect.

When folic acid replaced vitamin B₁₂, keto-acid excretion was reduced, but the dose required increased as vitamin C depletion progressed. A series of small doses of folic acid had a cumulative action. It is suggested that the actions of vitamin C and folic acid are closely linked in tyrosine metabolism.—V. R. Jackson.

525

VERNE, J., HEBERT, S. and BARBARIN, Y. **Étude cytochimique des rapports entre l'activité estérasiqne et l'acide ascorbique chez le cobaye. [Cytochemical study of the relation between esterase activity and ascorbic acid in the guineapig.]** *C.R. Soc. Biol.*, 1953, **147**, 412-413. [Inst. Nat. Hyg., Paris.]

Cytochemical study by means of the Gomori reaction with Tween showed that the esterase

activity in several guineapig tissues varied with the vitamin C status. In vitamin-C-deficient guineapigs, esterase activity was found only in the pancreas and intestine. In guineapigs receiving an excess of vitamin C there was a great increase of esterase activity, especially in the liver, intestine and lungs, but no activity appeared in tissues from which the enzyme is normally absent.

526

McKEE, R. W. and WALKER, J. K. **Oxygen consumption of adrenal slices from normal and scorbutic guinea pigs and the influence of added ACTH.** *Science*, 1953, **118**, 133-135. [Cancer Res. Inst., New England Deaconess Hosp., Boston, Mass.]

Oxygen consumption was measured in an atmosphere of O₂ with the slices of adrenal gland in an isotonic inorganic medium and glucose as substrate. The average O₂ consumption, in c. mm. per hr. per 100 mg. wet adrenal slice, was 86 for normal and 141 for scorbutic guineapigs. Addition of 2 mg. adrenocorticotrophic hormone to the Warburg vessel increased normal consumption by 50 per cent., but had no effect on slices from scorbutic animals.—W. Godden.

527

BACCHUS, H. and HEIFFER, M. H. **Urinary corticosteroids and 17-ketosteroids in ascorbic acid-deficient female guinea pigs.** *Amer. J. Physiol.*, 1953, **174**, 243-246. [Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

Of female guineapigs maintained on a scorbutogenic diet of Purina rabbit chow and tap water, one group received daily 1.33 mg. sodium ascorbate per 100 g. bodyweight by intraperitoneal injection and another group received saline. They were paired. Some of each group were used for blood studies, the remainder for a study of urinary steroids.

The deficient animals showed a progressive decrease in excretion of corticosteroids, but the decrease in excretion of 17-ketosteroids was preceded by a progressive and significant rise for the first 3 days, and the decrease was not significant until the ninth day. Total lymphocytes and eosinophils increased significantly, and total polymorphonuclear neutrophils decreased in deficient animals. There was no change in the blood picture of the non-deprived animals. Lipid depletion and other signs of damage occurred in the adrenal cortex of deficient animals.

Ascorbic acid deficiency is thought to be associated with increased breakdown of adrenal cortical hormone to 17-ketosteroids, and later with reduced cortical activity.—D. Duncan.

528

JONES, J. M., LLOYD, C. W. and WYATT, T. C. **A study of the interrelationships of maternal and fetal adrenal glands of rats.** *Endocrinology*, 1953, **53**, 182-191. [Dept. Obstet., State Univ. New York, Syracuse.]

Pregnant rats receiving a stock diet were killed on the twenty-first day of gestation and the maternal and foetal adrenal glands were removed for estimation of ascorbic acid and cholesterol. Values were compared with those for non-pregnant rats. In some animals the effect on these values was studied of exposure to cold, 4° to 6° C., for 12 hr., and of adrenocorticotrophic hormone or cortisone acetate, given over several hours up to a few hours before death.

After exposure to cold, adrenal cholesterol in non-pregnant rats decreased from 4.44 to 3.18 mg. per 100 g. tissue and in pregnant rats from 2.57 to 1.10, but in foetal adrenal glands it increased by 75 per cent. to 1.39 mg. per 100 g.

In non-pregnant rats intravenous injection of adrenocorticotrophic hormone, 0.04 I.U., caused a significant depletion of ascorbic acid, and higher doses had little further effect; adrenal cholesterol was reduced by 35 per cent. by 1.6 I.U. In pregnant rats, from 0.16 to 1.6 I.U. caused a decrease of 25 per cent. in cholesterol and of 50 per cent. in ascorbic acid. In the foetus ascorbic acid was little affected but cholesterol was increased by 58 per cent. when the mother received 0.16 I.U.; with 1.6 I.U. cholesterol was normal and ascorbic acid 25 per cent. below normal.

Administration of 30 mg. cortisone had no effect on the maternal adrenal glands, but in the foetus cholesterol was increased by 70 per cent. and ascorbic acid was unaffected. In the adrenal glands of non-pregnant rats cortisone had no effect on cholesterol and decreased ascorbic acid by 23 per cent. Treatment with cortisone followed by adrenocorticotrophic hormone caused greater decrease of cholesterol and ascorbic acid than with adrenocorticotrophic hormone alone.

It is concluded that adrenocorticotrophic hormone did not cross the placental barrier when given in moderate amounts or under conditions of moderate stress, but that adrenal cortical steroids secreted by the maternal tissues did so pass.

V. R. Jackson.

COSTE, F., DELBARRE, F. and LACRONIQUE, F. Variations du taux de l'acide ascorbique des endocrines sous l'influence des stimulines hypophysaires. Taux de l'acide ascorbique des testicules du rat en fonction de l'âge. [Variations in the level of ascorbic acid in the endocrine glands after stimulation of the anterior pituitary. Level of ascorbic acid in the testes of the rat as a function of age.] Variations du taux de l'acide ascorbique

ovarien, chez la rate, aux différents stades du cycle oestral. [**Variations in the ascorbic acid level of the ovaries in the female rat at different stages of the oestrous cycle.**] *C.R. Soc. Biol.*, 1953, 147, 608-611; 611-613. [Lab. Clin. Rhumatol., Fac. Méd., Paris.]

The ascorbic acid content of the young rat's testis, estimated by indophenol titration, decreased with age, particularly between 21 and 63 days of age. At the usual age of puberty, about 50 to 60 days in Wistar males, the curve reached the adult level of about 26 mg. per 100 g. tissue.

The ascorbic acid content of the ovary was fairly stable in post-oestrus and di-oestrus, decreased sharply in pre-oestrus and recovered during oestrus. It is concluded that the diminution was conditioned by follicular or folliculo-luteal hormones.—D. Duncan.

DE BASTIANI, G. and GRANATA, L. Azione diabetogena del trattamento contemporaneo con glucosio ed acido deidroascorbico, nel ratto albino. [**Diabetogenic action for the albino rat of simultaneous treatment with glucose and dehydroascorbic acid.**] *Boll. Soc. ital. Biol. sper.*, 1953, 29, 223-224. [Ist. Fisiol., Univ. Padua.]

Rats of about 100 g. weight were maintained on a normal diet. Twenty were given for from 50 to 60 days a peritoneal injection in 2 doses of glucose increasing from 0.5 to 3 g. Another 20 were treated for 15 days with from 15 to 20 mg. dehydroascorbic acid and then with glucose, as in the first group, as well. A third group of 10 was treated only with dehydroascorbic acid for from 65 to 75 days. Some rats were killed at intervals earlier. There was no change in the blood sugar level or histological appearance of the pancreas except in the rats given glucose and dehydroascorbic acid. In them the fasting blood sugar level was at first low but about the 30th day there was hyperglycaemia in 70 per cent. of the animals, which became progressively worse; in the pancreas there were changes of a diabetic nature, including atrophy of some of the islet tissue.—E. M. Hume.

BANERJEE, S., BELAVADY, B. and MUKHERJEE, A. K. **Effect of dehydroascorbic acid in rabbits.** *Proc. Soc. Exp. Biol. Med.*, 1953, 83, 133-135. [Dept. Physiol., Presidency Coll., Calcutta.]

Intravenous injections of 1 or 1.5 g. dehydroascorbic acid per kg. in rabbits caused profuse salivation and lachrymation, dilatation of the pupil and respiratory failure but, contrary to the findings of Patterson (Absts. 1901, Vol. 20; 1962, 4922, Vol. 21), did not cause a persistent high blood

sugar level or persistent diabetic type of glucose tolerance curve. The initial rise in blood sugar level could be prevented by a prior injection of dihydroergotamine methanesulphonate. The rabbits did not excrete sugar in the urine or show any histological change in the pancreas, adrenal or pituitary glands.—W. Godden.

535

MADRID GUTIERREZ, M. Variaciones de la ascorbinemia del conejo diabetizado con aloxano y con distintos regimenes alimenticios. [**Variations in blood ascorbic acid in the alloxan-diabetic rabbit on different diets.**] *An. Fac. Farm. Bioquím., Lima*, 1951, 2, 445-455. [Lab. Hosp. Militar, Univ. Nac. Mayor de San Marcos, Lima.]

Rabbits were made diabetic by injection of 125 mg. alloxan per kg. bodyweight; 150 mg. per kg. was lethal. Ascorbic acid was estimated in the blood of 6 animals before and up to 72 hr. after injection of alloxan. In all there was immediate diminution of the ascorbic acid content with slight further decrease occurring even up to 3 days after the injection. The findings are discussed with reference to their possible bearing on human diabetes.—A. M. Copping.

536

SAPEIKA, N. and PARKER, R. G. F. **Effect of senecio alkaloid pterophine on the structure and ascorbic acid of the rat liver.** *S. African J. Med. Sci.*, 1953, 18, 1-4. [Dept. Physiol., Univ. Cape Town.]

In continuation of earlier work (Abst. 443, Vol. 23) the liver lesions resulting from acute poisoning with the alkaloid, pterophine, from the plant *Senecio* are briefly described and further figures are given to show its effect in reducing the ascorbic acid content of the liver and adrenal glands.—W. Godden.

537

MOON, F. E. and McKEAND, J. M. **Observations on the vitamin C status and haematology of bracken-fed ruminants.** *Brit. Vet. J.*, 1953, 109, 321-326. [Edinburgh and East of Scotland Coll. Agric.]

A bullock fed on a mixture of hay and artificially dried bracken died of bracken poisoning after 44 days. Two sheep fed almost entirely on dried bracken survived for 125 days and 289 days, respectively. The second sheep received vitamin C subcutaneously [amount not stated] daily for 57 days during the 8th to the 16th week. A few haematological observations were made on the first sheep, and at weekly intervals on the second sheep during the last 5 months before death. In none of the animals was there any evidence of a

simple deficiency of vitamin C resulting from bracken feeding although there may have been increased destruction of the vitamin in the terminal stages of the intoxication. The occurrence of leucopenia was confirmed for the sheep, with an indication of deficiency of platelets in the terminal stages. The development of bracken poisoning in the second sheep was more clearly marked by a progressive fall in erythrocytes and haemoglobin.

W. Godden.

538

ALLISON, R. M. and DRIVER, C. M. **The effect of variety, storage and locality on the ascorbic acid content of the potato tuber.** *J. Sci. Food Agric.*, 1953, **4**, 386-396. [Crop Res. Div., Dept. Sci. Indust. Res., Lincoln, N.Z.]

During 2 successive years ascorbic acid was estimated by indophenol titration in potato tubers of 20 varieties before, and at monthly intervals after, storage in a clamp of commercial type. The average ascorbic acid content of the 20 varieties fell from 16.0 to 10.0 mg. per 100 g. fresh tissue over about 8 months in 1949. The results for 1950 were similar and are presented for the same

varieties grown in 4 different places. Variety had a significant relation to ascorbic acid content. An increase in ascorbic acid content was found after prolonged storage when sprouting had commenced; the possible causes are discussed.—P. C. Jowsey.

539

SHILO, YU. M. and RAKHIMOVA, G. N. Soderzhanie vitamina C v moloche kobyly. [**The vitamin C content of mare's milk.**] *Konevodstvo*, 1953, No. 4, 39-43. [Kharkov Sovkhoz "Put' Industrialisatsii".]

The mean value for vitamin C in the milk of all the mares examined was 91 mg. per litre with individual variations from 34 to 147. The vitamin C content changed during lactation; it was low in the spring, at the beginning of lactation, increased in summer and then fell again in the autumn. These changes are most probably the result of variation in the amount of vitamin C in the diet during these periods. The vitamin C content was not much affected by work, breed, or age.

OTHER VITAMINS

540

BENDER, A. E. and TUNNAH, E. J. **Vitamin T: growth and protein utilization in the rat.** *J. Sci. Food Agric.*, 1953, **4**, 331-333. [Crookes Laboratories, Ltd., Park Royal, London, N.W.10.]

Groups of young rats received a stock diet alone or supplemented with extra B vitamins or 1 mg. or 100 mg. per rat daily of dried medium from a 10-day culture of *Torula utilis* grown on a malt medium, to provide the so-called vitamin T complex.

Growth of groups on stock diet with or without extra B vitamins was similar. Addition of the vitamin T supplement had no effect on growth rate or utilisation of protein.

In a second experiment, adult rats were deprived of protein for 7 days and then given 0.12 or 0.24 g. N daily as wheat gluten or dogfish meal, alone or supplemented with 0.01 ml. or 0.25 ml. commercial vitamin T (Pharmazell, T Vitamin Goetsch). The vitamin T had no effect on the rate of repletion with vegetable or animal protein.

The claims of Goetsch (*Öst. zool. Ztschr.*, 1948, **1**, 533) and of Pototschnig (*Med. Klin.*, 1951, **46**, 987) that vitamin T accelerates growth and improves food utilisation and assimilation of proteins could not be substantiated.—V. R. Jackson.

Vol. 24, No. 1

[**Experiments with T-Vitamin Goetsch and skimmed milk for dystrophic pigs.**] *Berl. Münch. tierärztl. Wochenschr.*, 1953, **66**, 248-250. [Physiol. Inst., Tierärztl. Hochsch., Hanover.] English summary.

Three unthrifty piglets aged 15 weeks and weighing only from 13 to 14 kg. were given a diet of oats, barley, potato flakes and fishmeal, with Vigantol and a mineral mixture. One received no supplement, one received 1 litre skimmed milk daily and the third had daily 2 g. Tevita, a preparation of vitamin T. The pig receiving vitamin T showed 53 per cent., and the one having skimmed milk showed 14 per cent., greater increase than the pig having no supplement. In a further test two pairs of piglets were given vitamin T or skimmed milk as a supplement and again those receiving vitamin T showed greater weight increase and better condition than the others.—A. M. Copping.

546

- LOES, M. Vergleichende Untersuchungen über den enzymatischen Abbau der verschiedenen Stärkearten. [**Comparative studies on enzymic hydrolysis of different starches.**] *Ann. paediat.*, 1953, **181**, 1-16. [Kinderklin., Univ. Freiburg i. Br.] English and French summaries.

Before studying the digestibility of starches by pancreas amylase the method was investigated, since it seemed probable that discrepancies in reported results were caused by failure to maintain constant experimental conditions. The rate of hydrolysis of the starches was followed by Bertrand's reduction method and Krainick's iodine colour estimation. The enzymic hydrolysis of starches of potato, wheat, maize, rice, barley, rye and oats, with constant concentrations of enzyme and substrate, showed that potato starch was hydrolysed more rapidly and completely than any of the cereal starches, which were all hydrolysed at the same rate and to the same degree. The duration of boiling of the starch paste had no effect on the rate of hydrolysis.—M. B. Richards.

- JACKEL, S. S., SCHULTZ, A. S. and SCHAEDEER, W. E. **Susceptibility of the starch in fresh and stale bread to enzymatic digestion.** *Science*, 1953, **118**, 18-19. [Fleischmann Labs., Standard Brands, Inc., New York 51.]

Rate of digestion of bread crumb was measured by a modification of Jackel's method (*Cereal Chem.*, 1952, **29**, 190) in which α -amylase was replaced by pancreatin. For ordinary bread the rate fell steadily as storage time increased until after 160

hr. it was about 75 per cent. of that after 20 hr. When the bread had been baked with the addition of bacterial α -amylase there was no change in the rate of digestion after storage for up to 160 hr.

The reduction in the rate for control bread after storage is contrary to the earlier results of other workers (e.g., Abst. 3139, Vol. 13) and it is suggested that the difference may have arisen, not from a change in susceptibility of the starch to enzyme attack but, in those experiments where dispersion was not complete, to a change with age in its availability for enzymic digestion.

steatosis resistant to choline.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1830-1832; 1832-1834. [Ist. Chim. Biol., Univ. Naples.]

Of 20 rats, weighing from 150 to 200 g. and given subcutaneously on 2 successive days 0.75 mg. per 100 g. bodyweight of P dissolved in oil, 12 received a daily intraperitoneal injection of 65 mg. trypsin Merck on the same 2 days and one succeeding one; the others had no further treatment. All were killed on the fourth day. The percentage of fat in the fresh liver ranged from 5.76 to 9.06 in the animals given trypsin, and from 10.37 to 18.12 in those not given trypsin.

Sixteen rats were given a choline-free diet with 10 per cent. casein. After 3 weeks, for another week, all received 0.4 per cent. choline and 3 also received lipocaic, 6 received trypsin Merck and 2 received inositol, while 5 had no further addition. They were then killed. The fat percentage in the fresh liver ranged, in those given choline only, from 19.30 to 28.50. In the other 3 groups it did not differ significantly, ranging from 6.50 to 8.75. The failure of choline to protect against fatty liver on a low-protein diet was thus demonstrated.

Further studies on the cofactors of the liver tyrosine oxidase system.

The stability and activation of the liver tyrosine oxidase system. *J. Biol. Chem.*, 1953, **203**, 109-116; 605-612; 613-623. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The total tyrosine oxidase system of rat liver was completely extracted by 0.25 M sucrose solution. From experiments made with this extract at pH 7.4 and 37° C. in a Warburg apparatus, in which 2:6-dichlorophenolindophenol was used for the destruction of ascorbic acid, the involvement of ascorbic acid in the oxidation system previously reported by other workers (Absts. 1903, Vol. 20; 2102, Vol. 22; 2266, Vol. 23) has been confirmed. The evidence suggests that glutathione is also implicated, probably at a later stage in the system than ascorbic acid. Low concentrations of 2:6-dichlorophenolindophenol stimulated tyrosine oxidase; high concentrations totally inhibited it. Possible explanations of this finding are discussed.

Further experiments support the above findings; ascorbic acid stimulated the production of acetoacetate from homogentisic acid, but dichlorophenolindophenol inhibited this stage in the oxidation system. The addition of ascorbic acid, glutathione, low concentrations of dichlorophenolindophenol or extract of boiled fresh enzyme

Vol. 24, No. 1

significantly stimulated the activity of enzyme aged by incubation alone at 37° C. for 1 hr. When these substances were added in different combinations the effects were additive and closely approached the sum of the effects of the individual substances. Thus it would appear that ascorbic acid functions in two places in the tyrosine oxidase system and that glutathione and a labile substance for which 2:6-dichlorophenolindophenol can be a substitute are additional components of the system.

When liver tyrosine oxidase was aged at 5° C. in a stoppered flask or dialysed against distilled water at 5° C. for increasing lengths of time the loss of activity was the same for 24 hr., but after this was greater in the dialysed system. Ascorbic acid increased the activity of both dialysed and aged enzyme preparations, but dichlorophenolindophenol increased only the latter. The activity of dialysed enzyme could be restored by a combination of ascorbic acid, glutathione and an extract of heated fresh enzyme. This latter extract contains a substance, anionic in nature, which is necessary for maximum tyrosine oxidation. The interrelationships of these substances for tyrosine oxidase are discussed and their possible sites of action in the oxidation of tyrosine to acetoacetate and fumarate are tentatively indicated.

RICHERT, D. A. and WESTERFELD, W. W. **The effect of diet on tissue choline oxidase.** *J. Biol. Chem.*, 1952, **199**, 829-833. [Dept. Biochem., Med. Coll., State Univ. New York, Syracuse.]

Adult rats maintained on dog chow showed normal liver and kidney choline oxidase activity. Weanling rats had about half this activity, but on a diet containing 21 per cent. casein, with riboflavin, vitamin B₁, pyridoxine, pantothenate, nicotinic acid and choline, adult levels were reached in 2 to 4 weeks. In the experiments described, weanling rats were fed on casein diets deficient in one of the vitamin constituents for 2 to 4 weeks.

A riboflavin-deficient diet gave low values for liver choline oxidase. Omitting choline from the diet decreased kidney and liver choline oxidase in the rats, which survived for 9 days. Diets deficient in vitamin B₁ or pyridoxine produced little change in the choline oxidase activity.

The reduction of dietary protein to 8 per cent. produced a 50 per cent. decrease in liver choline oxidase in both adult and weanling rats. Addition of 0.1 per cent. iodinated casein to the diet gave a consistent decrease in both liver and kidney choline oxidase.—A. Iggo.

HEATH, D. F. and PARK, P. O. **An irreversible choline-esterase inhibitor in white clover.** *Nature*, 1953, **172**, 206. [Pest Control, Ltd., Harston, Cambridge.]

The inhibitor was extracted from white clover strain S100, untreated or treated with radio-active octamethylpyrophosphoramide.

The total inhibitor activity was estimated by the method of Michel (Abst. 1400, Vol. 20) and the results, expressed as the volume of solution in ml. extracted from 1 kg. clover which induced 50 per cent. inhibition in a serum solution after incuba-

tion for 30 min. at 25.6° C., were: untreated samples 32 to 4550, treated 2140 to 10,620. The considerable variation may be accounted for by adsorption on the chlorophyll, which was removed during processing, or by variation due to stage of growth.

The substance does not inhibit cholinesterase by producing cyanide, but it may be identical with one of the cyanogenetic compounds present in clover which are believed to cause bloat in sheep and cattle.—P. C. Jowsey.

TUBA, J., SILUCH, K. A., ROBINSON, M. I. and MADSEN, N. B. **The relationship of dietary factors to rat serum alkaline phosphatase. 4. The effect of dietary oxalate.** *Canad. J. Med. Sci.*, 1952, **30**, 515-519. [Dept. Biochem., Univ. Alberta, Edmonton.]

Twenty-four growing rats in 4 groups were maintained on synthetic diets for 6 weeks. Diet 1 contained 0.5 per cent. Ca as lactate, which in diet 2 was replaced by sucrose containing 0.09 per cent. Ca. Diet 3 contained 0.5 per cent. Ca and dried rhubarb which provided 0.95 per cent. oxalate, and diet 4 contained 0.95 per cent. oxalate as the Na salt. Serum alkaline phosphatase, serum P, Ca and Mg and the ash content of the tibia were estimated.

A low-Ca diet with or without oxalate produced increases in serum alkaline phosphatase, and serum P and Mg and ash content of tibia indicated that the animals were rachitic. This was confirmed by staining the tibiae with silver nitrate and examining the epiphyseal plate.—A. Iggo.

565

TUBA, J. and ROBINSON, M. I. **The response of intestinal alkaline phosphatase of fasted rats to forced feeding of fat.** *J. Biol. Chem.*, 1953, **203**, 947-951. [Dept. Biochem., Univ. Alberta, Edmonton.]

Adult male rats were fasted for 2, 6 or 12 days and then received 1 ml. olive oil or 1 ml. water by mouth. They were killed after 8 hr. and alkaline phosphatase was estimated in the blood serum and in the first 10 cm. of the intestine from the pylorus. After 2 days' fast both serum and intestinal phosphatase had fallen sharply and they continued at a low level for the longest periods of fasting. After olive oil serum alkaline phosphatase was elevated at all stages of fasting, but the response was smaller as fasting was prolonged. After 2 days' fasting, intestinal phosphatase was much increased after ingestion of olive oil, but not after 6 or 12 days' fast. N in both liver and intestine fell steadily as fasting continued.

MATTENHEIMER, H. Die Dephosphorylierung von Casein und Phosphopepton durch Phosphoprotein-Phosphatase. [The dephosphorylation of casein and phosphopeptone by phosphoprotein phosphatase.] *Hoppe-Seyler's Ztschr.*, 1953, **292**, 276-286. [Physiol. Chem. Inst., Freie Univ. Berlin.]

In a series of experiments designed to investigate more closely the differences between phosphoprotein phosphatase and phosphomonoesterase, it was shown that phosphopeptone, casein, α -casein and β -glycerophosphate could be dephosphorylated by enzyme solutions prepared from pig's stomach, rat's liver, and human prostate and ejaculate. That phosphomonoesterase and phosphoprotein phosphatase are not identical enzymes was shown

by the selective inactivation of phosphomonoesterase by incubation with alkali and the quantitative separation of the 2 enzymes, by means of electrodialysis, in an extract of the mucous membrane of sow's stomach. β -Glycerophosphate was not hydrolysed by phosphoprotein phosphatase; on the other hand, there were indications of a partial dephosphorylation of phosphopeptone and α -casein by phosphomonoesterase. Stomach cathepsin showed no phosphatase activity with the substrates used. The enzymatic dephosphorylation of phosphopeptone and casein was scarcely affected by simultaneous catheptic breakdown of the substrates.

LUKSHIN, V. V. Izmenenie sekretornoj funktsii zheludka lozhadi pod vliyaniem kachestvenno

razlichnykh ratsionov kormleniya. [Changes in the secretory function of the stomach of horses as a result of qualitative differences in the rations.] *Konevodstvo*, 1953, No. 4, 31-38.

The effect of 3 diets, hay and oats, "Kombi korm", or pasturage, on the secretory functions of the stomach of horses was studied by analysing the stomach contents, blood and urine.

In general the experiments showed that the function of the digestive organs depends on the properties of the diet. A constant diet leads to adaptation in quantity and composition of digestive juices. When the horses were maintained on hay and oats for a long time, reduced acid secretion in the stomach led to functional and organic disorders.—W. Hughes.

571

PARTHASARATHY, D. and PHILLIPSON, A. T. **The movement of potassium, sodium, chloride and water across the rumen epithelium of sheep.** *J. Physiol.*, 1953, **121**, 452-469. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Studies on the absorption of Na, K, chloride and water from the rumen of sheep supported the evidence that rumen epithelium is a selective membrane. The venous - arterial differences between rumen and carotid blood for K, Na and Cl proved a reliable indication of whether significant absorption was occurring. No absorption of Na and K took place until their concentrations in the rumen exceeded those of carotid blood. Chloride was absorbed from the rumen against a concentration gradient if the concentration was 135 mg. per 100 ml. or more, but chloride in the rumen increased when concentrations of less than 100 mg. per 100 ml. were present. No relation was found between the absorption of acetate or propionate and the presence or absence of K. The absorption of fatty acids was influenced only by reduction of pH or introduction of 0.002 M mercuric chloride, which decreased the absorption of chloride, water and fatty acid, but did not affect that of Na and K. The experiments showed that rumen epithelium is readily permeable to water. Absorption of water occurred from solutions of 0.165 M concentration or less, but the volume of solutions of 0.33 M increased when they were introduced into the rumen.—M. B. Richards.

CLARK, C. H. **The nerve control of rumination and reticulo-ruminal motility.** *Amer. J. Vet. Res.*, 1953, **14**, 376-384. [Dept. Vet. Physiol. Pharmacol., Coll. Vet. Med., Ohio State Univ., Columbus.]

Section of one cervical vagal trunk in a sheep caused a slight decrease in the speed of contraction of the reticulum and the dorsal sac of the rumen. In 6 decerebrate sheep no spontaneous movement of the reticulum was seen; but spontaneous swallowing movements occurred. Decorticated sheep lived up to a year and the most noticeable manifestation was blindness; movements of the reticulum and rumen and the time daily spent in eating and ruminating were normal. Frontal lobectomy was performed in 2 sheep, and in these animals, which lived 63 days and 6 months, the time spent in ruminating was doubled, but the time spent in eating and the quantity of food eaten were normal. Destruction of areas at the base of the brain oral to the anterior commissure and ventral to the genu of the corpus callosum by local injections of methanol increased the length of the time spent in ruminating. One animal ruminated continuously for 24 hr. and in another the co-ordination between regurgitation and reticulum contractions was lost. Damage to the left hypothalamic nuclei was found in the latter. It is suggested that an area of the subcortical tissue anterior to the stalk of the pituitary is intimately connected with rumination and movements of the reticulo-rumen sacs.—A. T. Phillipson.

WILLIAMS, V. J., NOTTLE, M. C., MOIR, R. J. and UNDERWOOD, E. J. **Ruminal flora studies in the sheep. 4. The influence of varying dietary levels of protein and starch upon digestibility, nitrogen retention, and the free micro-organisms of the rumen.** *Austral. J. Biol. Sci.*, 1953, **6**, 142-151. [Inst. Agric., Univ. W. Australia, Nedlands.]

For previous papers see Absts. 624, Vol. 20; 809, Vol. 21; 5216, Vol. 21.

Nine diets were designed to give no starch or 99 or 149 g. daily, and about 14, 60 or 80 g. protein daily. Twelve sheep from 2 to 2½ years old were used.

Starch depressed the numbers of free bacteria present in the rumen liquor on the low-N diets; this effect was less, and not statistically significant, on intermediate-N rations, and was abolished at the high-N level. Increasing the protein of the ration did not increase the bacterial counts when no starch was given, but produced a significant rise in rations containing starch.

The addition of starch at all levels of protein feeding brought about little difference in the

N.A. and R., January 1954

digestibility of dry matter, but at all levels of starch feeding protein significantly increased dry matter digestion.

It is concluded that the proportion of the total protein in the ration converted to bacterial protein, on the assumption that this is reflected by the bacterial counts, is not a constant, but diminishes as the intake of protein increases, for bacterial counts increased from 27 to 58 millions per c.mm. while protein intakes increased by a wider ratio, from 14.2 to 82.3 g. daily.—A. T. Phillipson.

VAN LIERE, E. J., FANG, H. S. and NORTHUP, D. W. **Effect of semi-starvation on propulsive motility of the small intestine.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 98. [Dept. Physiol., Sch. Med., W. Virginia Univ., Morgantown.]

Twelve rats were underfed until they had lost on the average 39 per cent. of their weight. They were then paired with control rats and after 12 hours' starvation were given 2 ml. of a mixture of 10 per cent. powdered charcoal suspended in a 10 per cent. solution of gum acacia. The charcoal traversed 72 per cent. of the gut in the controls and 91 per cent. in the semi-starved rats.

GIL', S. A. O vliyanii raznovidnostei kislogo vosstanovlennogo moloka na sekretornuyu, motornuyu i vsasyvatel'nuyu funktsii tonkikh kishok. [**Effect of different kinds of sour milk made from powder on secretory, motor, and absorptive function of the small intestine.**] *Vop. Pediat.*, 1952, **20**, No. 6, 32-38. [Khar'kov Nauch-Issled. Inst. Okhran. Mater i Detstva.]

Kefir prepared from whole condensed milk tends to pass through the stomach and small intestine more evenly and slowly than milk acidified with lactic acid. When dogs were fed on kefir, less chyme appeared from intestinal fistulae during the whole of the digestion period than when whole milk acidified with lactic acid was used. When puppies were fed on kefir the chyme moved more rapidly along the digestive tract than in young dogs; there was very little difference between the rate of flow of chyme in puppies and young dogs when acid milk was used. Protein, fat and minerals were absorbed more rapidly from the small intestine when kefir was used. Carbohydrates were absorbed well from both types of milk, the uptake being greater in young dogs than in puppies.—W. Hughes.

577

BRAKSH, T. A. Ob usvoenii pishchi pri dlitel'nom medikamentoznom sne. [**Assimilation of food in prolonged sleep therapy.**] *Klin. Med.*,

Vol. 24, No. 1

Mosk., 1952, **30**, 85-86. [Lab. Otdel. Fiziol., Inst. Pit., Akad. Med. Nauk SSSR.]

White rats fed on casein, starch, fat, salt mixture, dry yeast and fish oil were anaesthetised with sodium amytal, a subcutaneous injection of 250 mg. per kg. bodyweight twice a day. They were kept asleep for 10 days. No difference could be detected in the digestibility of fat, protein, and carbohydrate before, during or after sleep. There was very little difference in digestibility of food given to animals suffering with ulcers before, during and after the sleep treatment in which chloral hydrate, sodium amytal and luminal were used as narcotics. A slight decrease in digestibility of fat occurred towards the end of sleep.

SCHLÜSSEL, H. and SUNDER-PLESSMANN, L. Zur Lokalisation der Eiweissresorption im Magen-Darmtrakt. Tierexperimentelle Untersuchungen mit S³⁵-markiertem Hefeeiweiss. [**Location of protein absorption in the gastro-intestinal tract. Animal experiments with yeast protein labelled with ³⁵S.**] *Klin. Wochenschr.*, 1953, **31**, 545-547. [Med. Klin., Univ. Cologne.]

It had previously been shown that radio-active S introduced into living *Torula utilis* was present only in the sulphur amino-acids (Absts. 2472, Vol. 21; 1016, Vol. 22). Such radio-active yeast was prepared in 34 portions, each containing 50 μ C. of activity, which were administered to 34 female rats of weight from 70 to 100 g., which had fasted for 12 hr. After 2, 4, 6, 8 or 10 hr. the animals were bled under ether anaesthesia and killed. The liver and gastro-intestinal tract were removed and washed. The small intestine was divided into 4, and the colon into 2, portions of the same length. The tissues were dried and ³⁵S was estimated in them. The mean results for 6 or 7 rats are expressed as percentages of the total dose.

The peak of absorption was reached in the duodenum and in all parts of the small intestine and colon at the same time. For the whole tract the time of maximum absorption ranged from 2 to 7 hr. after administration, with the activity decreasing in both directions from the duodenum to the rectum and to the stomach. Most of the absorption was from the small intestine.

E. M. Hume.

579

AGAR, W. T., HIRD, F. J. R. and SIDHU, G. S. **The active absorption of amino-acids by the intestine.** *J. Physiol.*, 1953, **121**, 255-263. [Dept. Physiol., Univ. Melbourne, Victoria.]

A loop of about 40 cm. of rat small intestine was mounted in a modified Fisher and Parsons apparatus (Abst. 4446, Vol. 19) and a glucose-bicarbonate

solution gassed with 5 per cent. CO₂ in O₂ was circulated inside and outside the loop. Amino-acids or peptides were added to the inner fluid or to both fluids and after 1 or 2 hr. the fluids were measured and analysed.

L-Histidine and L-phenylalanine were removed from the lumen faster than water and against the concentration gradient. D-Histidine, L-glutamic acid and D-phenylalanine were transferred at the same rate as, or more slowly than, water. There were net losses of L-phenylalanine and L-histidine during the first 15 min., and a small net gain of L-glutamic acid; the histidine could be recovered from the gut wall, and it was assumed that these amino-acids had to saturate the cells before appearing in the outer fluid. In the presence of cyanide or dinitrophenol, L-histidine was transferred at the same rate as water.

Glycyl- and leucylglycine were partly transferred as such, but were mostly hydrolysed in the inner fluid and the amino-acids were transferred. Glycylglycylglycine was not transferred but hydrolysed, glycine and small amounts of glycylglycine appearing in the outer fluid.—C. Warner.

BERNHARD, K. and RITZEL, G. Galle und Fettresorption. [Bile and fat absorption.] *Helv. physiol. pharm. Acta*, 1953, **11**, 166-170. [Physiol. Chem. Inst., Univ. Basle.] English summary.

In experiments with labelled fat on rats with gall-bladder and thoracic duct fistulae, both faeces and lymph gave lipids with greatly reduced deuterium content. In animals with thoracic duct fistulae only, and normal flow of bile into the intestine, the deuterium content of the lymph lipids was little altered. The results show that fat is absorbed by rats even in the absence of bile, and confirm previous findings on man and dog that in the absence of bile endogenous fat is secreted into the intestine, with dilution of the food fats. An important, but hitherto unknown, function of bile in fat absorption is the prevention of this secretion of endogenous fat into the intestine.—M. B. Richards.

582

DE LANGEN, C. D. **Steatorrhoea and the intestinal circulation.** *Doc. Med. geograph. trop.*, 1953, **5**, 157-167. [Dept. Internal Dis., Univ. Hosp., Utrecht.]

Idiopathic steatorrhoea is considered to be a result of faulty absorption, which can be brought about, as has been shown in animal experiments, by any condition which affects the circulation. The mechanism of absorption is discussed in detail; it is considered to be a biphasic process comparable with secretion in the kidneys. Conditions affecting intestinal circulation and absorption are reviewed.—L. Wills.

583

REISER, R. and WILLIAMS, M. C. **Dihydroxyacetone esters as precursors of triglycerides during intestinal absorption.** *J. Biol. Chem.*, 1953, **202**, 815-819. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Rats were fed on monopalmitin and 1-palmitoxy-3-hydroxyacetone, each labelled with ¹⁴C in the carboxyl group of the palmitic acid and in carbon 3 of the alcohols. Thoracic duct lymph was collected.

Monopalmitin was hydrolysed in the intestine to the extent of 73 per cent. and appeared in the thoracic duct lymph in the form of triglycerides. Palmitoxyhydroxyacetone was hydrolysed to about the same degree in the intestine; triglycerides appeared in the lymph, indicating that reduction and esterification had taken place. It is suggested that esterification of dihydroxyacetone with subsequent reduction and esterification may be the normal path of triglyceride synthesis during fat absorption.—G. A. Garton.

HERNANDEZ, H. H., PETERSON, D. W., CHAIKOFF, I. L. and DAUBEN, W. G. **Absorption of cholesterol-4-C¹⁴ in rats fed mixed soybean sterols and β -sitosterol.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 498-499. [Dept. Physiol., Sch. Med., Univ. California.]

Rats of Long Evans strain, fitted with thoracic duct cannulae, were fed on diets containing cottonseed oil and β -sitosterol or soya bean sterols, with or without simultaneous administration by stomach tube of ¹⁴C-labelled cholesterol. The percentage of ¹⁴C activity recovered from the lymph was estimated periodically over 48 hr. and the amount of ¹⁴C-labelled cholesterol ester in the lymph was calculated.

Simultaneous feeding of soya bean sterols or sitosterol with labelled cholesterol occasioned a marked reduction in ¹⁴C recoveries from thoracic

N.A. and R., January 1954

duct lymph and in the proportion of esterified cholesterol in the lymph. When the diet contained only cottonseed oil and labelled cholesterol, about 50 per cent. of the lymph cholesterol was esterified.—G. A. Garton.

FOURNIER, P. and DUPUIS, Y. (with BOURDEAU, A.) Une méthode d'évaluation indirecte du taux de l'absorption des composés phosphorés à différents niveaux du tube digestif. [An indirect method of estimating the absorption of phosphorus compounds from different parts of the digestive tract.] Le sort des composés phosphorés de la ration dans les diverses parties du tube digestif du rat adulte. [The fate of phosphorus compounds in the ration in different parts of the digestive tract of the adult rat.] *J. Physiol., Paris*, 1953, **45**, 443–449; 451–461. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

Adult male rats were divided into 3 groups of 3. The 3 diets used differed only in the amounts of titanium oxide added, at the expense of wheat flour, at 0.3, 1.0 and 3.0 per cent., respectively. Each diet contained approximately 240 mg. P per 100 g. The rats were killed after 2 weeks and coefficients of absorption of P were estimated for different segments of the digestive tract. The

concentration of TiO_2 did not affect the coefficient of P absorption, which was small in the stomach, negative in the first 3/4 of the small intestine and remarkably constant, at about 53, in the remainder of the digestive tract. The rate of transit of TiO_2 was similar to that of P, and TiO_2 is considered to be a useful marker for studies of P absorption in the rat.

Adult male rats, in 2 groups of 4, received diets differing only in P content; the first contained 245, the second 18 mg. P per 100 g. Each rat received 18 g. food daily. Rats were killed when the P : TiO_2 ratio in the faeces had been constant for several days. Changes in P concentration in different parts of the digestive tract were estimated from the changing P : TiO_2 ratio. The great increase in P concentration in the upper part of the small intestine is due to endogenous P, the output of this being estimated by difference between the concentrations observed on the medium- and low-P diets. The coefficient of P absorption is quite constant in the caecum, large intestine and faeces and the stability of the P : TiO_2 ratio indicates that there is no P absorption below the small intestine. Absorption occurs in the stomach and all along the small intestine. Endogenous P represents about 30 per cent. of the total P excreted in the faeces.—D. Duncan.

MURTY, V. N. and KEHAR, N. D. Physiological studies on the blood of domestic animals 3.

The normal blood picture of the Kumaoni bullock. *Indian J. Vet. Sci.*, 1952, **22**, 251-255. [Animal Nutrit. Div., Indian Vet. Res. Inst., Izatnagar.]

The average values and standard errors found in a study of 24 healthy adult Kumaoni bullocks maintained on a standard basal ration of rape cake and wheat bhoosa were: Hb 7.4 ± 0.18 per cent., red cell count $6.5 \pm 0.24 \times 10^6$ per c.mm., white cell count $8.4 \pm 0.33 \times 10^3$ per c.mm., cell volume 35.3 ± 1.34 per cent., mean corpuscular volume 54.6 ± 1.17 μ , mean corpuscular Hb 11.6 ± 0.29 μ g., mean corpuscular Hb concentration 21.2 ± 0.40 per cent., total reducing sugars 88.1 ± 2.06 mg. per 100 ml. blood, serum protein 6.79 ± 0.25 g. per 100 ml. serum. All the following are in mg. per 100 ml. serum: Ca 10.5 ± 0.10 , inorganic P 6.8 ± 0.20 , Mg 2.35 ± 0.11 , Na 369 ± 15.24 , K 14.0 ± 0.28 , Cl 385 ± 4.42 .

The data are compared with those for Hariana and Dhanni bullocks in some instances. [The figures in Table 2 are wrong in several places.]

P. C. Jowsey.

REYNOLDS, M. **Plasma and blood volume in the cow using the T-1824 hematocrit method.** *Amer. J. Physiol.*, 1953, **173**, 421-427. [Dept. Physiol., Sch. Vet. Med., Univ. Pennsylvania, Philadelphia.]

Plasma and blood volumes were found to be relatively less in cattle than those found in rats, rabbits, dogs, sheep and man with the same method. Plasma volumes of about 38 mg. per kg., corrected haematocrit values of 29 to 32 per cent. and blood volumes of 52 to 57 ml. per kg. are recorded.—H. G. Bray.

593

MUKHERJEE, D. P. and BHATTACHARYA, P. **Seasonal variation in haemoglobin and cell-volume contents in rams and goats.** *Indian J. Vet. Sci.*, 1952, **22**, 191-197. [Animal Genetics Sect., Indian Vet. Res. Inst., Izatnagar.]

Blood samples were collected at fortnightly intervals for 12 months from 9 rams and 8 goats. Summer conditions of high air temperature and high relative humidity and rainfall caused a reduction of Hb and cell volume. In spring, when air temperatures were moderate and relative humidity was low, this was reversed.

The trends were similar to those found by other authors for the seasonal variations in sperm quality of rams and goats.—P. C. Jowsey.

594

WATSON, D. F. **Studies on the hemoglobin content of sheep blood in the Sierra of Peru.** *Amer.*

J. Vet. Res., 1953, **14**, 405-407. [Pachacayo, Peru.]

Hb was estimated in healthy animals at altitudes of between 12,000 and 15,000 ft. in the Andes. The following average values, in g. per 100 ml., were obtained over 10 months: yearling ewes 15.85, yearling wethers 15.62, 2-year-old wethers 16.52. Changes in Hb level occurred during and after pregnancy and during illness and recovery from disease. Sheep imported from areas at or near sea level generally had initial Hb levels between 8.0 and 10.0 g. per 100 ml. and over 3 to 4 months there was a steady rise to levels similar to those quoted.—P. C. Jowsey.

597

BÉNARD, H., DANTCHEV, D. and GAJDOS, A. **Étude des proportions de deux variétés d'hémoglobuline au cours de la réparation de certaines anémies expérimentales chez le lapin. [Study on the proportions of two kinds of haemoglobin during recovery from experimental anaemia in the rabbit.]** *C.R. Soc. Biol.*, 1953, **147**, 601-602. [Clin. Méd., Hôtel-Dieu.]

Intense anaemia, from which spontaneous recovery occurred in about a fortnight, was produced in rabbits by bleeding on 3 successive days or by injection of phenylhydrazine. In some rabbits recovery was accelerated by administration of folic acid or of vitamin B₁₂.

In normal rabbits the proportion of alkali-resistant Hb varies between individuals but is constant in each rabbit. The proportion was unchanged during the development of anaemia, but during the replacement of corpuscles only alkali-resistant Hb was produced. The non-resistant type remained at its lowest level until

N.A. and R., January 1954

the cell count was again normal. It is suggested that when necessary the more rapidly formed alkali-resistant Hb takes precedence in formation.

KARTE, H. Elektrophorese der Blutserumproteine im Säuglingsalter. [Electrophoretic study of the blood serum protein in infants.] *Ztschr. Kinderheilk.*, 1953, **73**, 467-486. [Kinderklin., Univ. Göttingen.]

Data from 500 electrophoretic serum analyses and total protein estimations on 280 infants undergoing clinical treatment, and from over 40 serum investigations on healthy infants and newborn babies, provided for discussion of serum protein changes in the disorders of infancy. One of the most striking findings was the occurrence in infants of low blood protein values due to decrease of globulins, especially γ -globulin. The exudation of large amounts of blood plasma into inflamed tissue gave rise to low blood protein values, especially in young infants. Healthy infants had higher α -globulin and lower γ -globulin values than

children and adults. This difference was accentuated in the presence of inflammatory conditions, which led frequently to an increase of α -globulin and a decrease of γ -globulin.—M. B. Richards.

602

PASSARO, G. L'equilibrio elettrolitico nel lattante affetto da distrofia da carboidrati. [Electrolytic equilibrium in the infant with carbohydrate dystrophy.] Il volume del liquido extracellulare nel lattante affetto da distrofia da carboidrati. [The volume of extracellular fluid in the infant with carbohydrate dystrophy.] Il volume del liquido extracellulare nel lattante distrofico. [The volume of extracellular fluid in the dystrophic infant.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 245-248; 248-251; 251-253. [Ist. Clin. Pediat., Univ. Rome.]

The proteins and electrolytes of the plasma, except Mg, were estimated in 9 children aged from 12 to 24 months who had been fed for some months previously on a diet almost exclusively of carbohydrate and fat. They were underweight, with oedema and signs of multiple vitamin deficiency. The protein values were low in all except one child. The values for all the electrolytes were low, so that the osmotic pressure of the plasma was low, but the alkali reserve was normal. After recovery the values had returned to normal.

Extracellular fluid was estimated with Na thiocyanate in 9 children from 11 to 27 months old with carbohydrate dystrophy and similar to those just described. The value taken as normal was 26 per cent. of the bodyweight. The values found before treatment ranged from 27.2 to 41.5. On treatment they slowly fell towards normal.

The same tests were made on premature infants aged from 1 to 3½ months, and the values found for extracellular fluid ranged from 34.3 to 44.9 per cent., being near to those for normal full-term infants at birth; they gradually fell with lapse of time.

For 30 infants aged from 3 to 39½ months, suffering from general undernutrition, the values for extracellular fluid ranged from 23.6 to 39.5 per cent. They were directly related to the severity of the undernutrition and came down on treatment, but less readily than in children with carbohydrate dystrophy.—E. M. Hume.

ANTONINI, F. M. and PIVA, C. Miglioramenti alla tecnica di elettroforesi su carta. [Improvements in the technique of electrophoresis on

paper.] Il frazionamento elettroforettico del siero di alcuni animali. [Electrophoretic fractionation of the serum of certain animals.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1885-1886; 1887-1889. [Clin. Med., Univ. Florence.]

Modifications of manipulation are described in detail. Amidochwarz 10B Bayer or Naphthalene Black I.C.I. is preferred to bromophenol blue for colouring the strips of paper.

With the method described, the serum of young healthy animals was examined. For the monkey (*Rhesus macaca mulatta*), horse, calf, pig, dog, cat, rabbit, guineapig, white rat, mouse, fowl and edible frog electrophoretic diagrams are given, and values are set out for total protein, albumin: globulin ratio and protein fractions numbered from 1 to 6 in order of decreasing mobility. Human serum was used for comparison.

GLEASON, T. L. and FRIEDBERG, F. **Filter-paper electrophoresis of serum proteins from small animals.** *Physiol. Zool.*, 1953, **26**, 95-100. [Dept. Biol., Catholic Univ. America, Washington, D.C.]

Electrophoresis of blood serum proteins on paper strips showed the presence of 5 components in the serum of opossum, rat and mouse. In rats infected with *Trichinella spiralis* and in mice with mammary carcinoma there was a decrease of the albumin component. Serum from turtle and mud puppy showed 7, from frog 10, and from salamander 3 components; the total protein content was less and the rate of migration of the proteins was slower than in mammalian serum.

CASANOVA CH., J. Determinación cuantitativa directa de colesterolemia total siguiendo la técnica de Sols. [Direct quantitative estimation of total cholesterol in blood by the method of Sols.] *An. Fac. Farm. Bioquim.*, Lima, 1951, **2**, 487-497. [Lab. Clin., Hosp. 2 de Mayo, Lima.]

The technique of Sols (Abst. 75, Vol. 18) was used for the first time in Peru to estimate total cholesterol in blood. In 12 healthy subjects the blood cholesterol lay between 129 and 181, with a mean of 157 mg. per 100 ml. serum. In 16 patients with chronic cholecystitis the values ranged from 164 to 310, average 221 mg. per 100 ml. serum. In 8 patients with gastric ulcer, the values were from 110 to 181, average 150 mg. The results for patients with other disorders did not give conclusive data, but 3 with diabetes gave 177, 212 and 293 mg., values above normal.

WALKER, W. J., LAWRY, E. Y., LOVE, D. E., MANN, G. V., LEVINE, S. A. and STARE, F. J. **Effect of weight reduction and caloric balance on serum lipoprotein and cholesterol levels.** *Amer. J. Med.*, 1953, **14**, 654-664. [Dept. Med., Peter Bent Brigham Hosp., Boston, Mass.]

Of 39 subjects, 29 had cardiovascular disease and the remaining 10 were obese. Twenty-eight were male, and ages ranged from 29 to 68 years.

In a preliminary period subjects were asked to continue their usual diets and maintain their body-weights. After this, energy intake was restricted to 1000 Cal., with 100 g. protein, 50 g. fat and 100 g. carbohydrate. Two eggs were taken daily to ensure a cholesterol intake of 60 mg. A weight loss of 2 lb. weekly was the aim. The weight-losing period was considered ended when a subject failed to lose $\frac{1}{3}$ lb. weekly. A weight-maintenance period followed in which protein and carbohydrate were added to the reducing diet. During this period 20 subjects were told to omit the 2 eggs and to avoid other cholesterol-rich foods for 2 months. Total cholesterol and S_f 12-20, S_f 21-35 and S_f 35-100 lipoproteins were estimated in serum at intervals.

The rate of weight loss varied. The duration of the weight-losing period ranged from 15 to 277 days, mean 106. Weight loss ranged from 7 to 40 lb., mean 19. It was associated with reduction of the 3 types of lipoproteins and cholesterol in most instances. The degree and duration of the reduction were directly related to the initial level of S_f 12-20. The degree of initial obesity was not a determinant of serum lipid changes, and rate of weight loss was only slightly concerned. In the 20 subjects whose cholesterol intake was restricted, serum lipids were not significantly different during restriction from the values obtained during the time of ample intake.

The effect of positive energy balance was studied in 2 subjects. They were given a low-fat, low-cholesterol diet for 2 weeks. The diet was then forcibly fed to produce a weight gain of at least 1 lb. daily. One subject gained 10 lb. in 11 days, the other 11 lb. in 9 days. Significant increases in serum lipoproteins and cholesterol resulted.

It is concluded that if high serum lipid levels contribute to the causation of atherosclerosis, weight reduction is a proper treatment for this disease.—F. C. Aitken.

MARFORI-SAVINI, L., VULTERINI, S., MAGALINI, S. and COLTORTI, M. **The serum lipoproteins (by salting out with sodium sulphate) in subjects suffering from coronary atherosclerosis.**

N.A. and R., January 1954

Acta med. scand., 1953, **146**, 148-156. [Ist. Clin. Med. Gen., Univ. Rome.]

The subjects were all men aged 40 to 60 years, 11 normal and 9 suffering from coronary arteriosclerosis, but able to work. Blood cholesterol values were similar in both groups, 223 ± 12 mg. per 100 ml. for normals and 217 ± 15 mg. for those with arteriosclerosis. Blood samples were collected in the fasting state and estimations were made on serum. Protein and cholesterol in the different fractions are tabulated and subjected to factorial analysis.

Although the number of subjects is small the results suggest a decrease in serum albumin in arteriosclerosis and an increase in serum globulin, especially in the fraction salted out by 26 per cent. Na_2SO_4 . The cholesterol of the albumin fraction was lower in arteriosclerosis, quite independently of total albumin and cholesterol levels, although these levels also showed interaction with albumin-bound cholesterol.—D. Duncan.

MAN, E. B. and PETERS, J. P. **Variations of serum lipids with age.** *J. Lab. Clin. Med.*, 1953, **41**, 738-744. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Total cholesterol, lipid P and total fatty acids were estimated at intervals of 10 to 20 years in blood serum from 7 men and 9 women whose ages ranged from 20 to 48 years at the first and from 30 to 65 years at the final examinations. Although significant increases were more frequent than decreases, no lipid component showed a change consistent with advancing age. The findings are discussed in comparison with those of other workers.—D. Harvey.

HAGBERG, B. **The iron-binding capacity of serum in infants and children.** *Acta paediat.*, 1953, **42**, Suppl. 93, pp. 80. [Clin. Paediat., Univ. Hosp., Upsala.] French, German and Spanish summaries.

The first chapter of this monograph is a general review of iron metabolism. The original Vahlquist method (Abst. 3163, Vol. 13) of estimating serum Fe has been modified for use with 0.3 ml. in place of 2 ml. serum.

Sera from 54 healthy adults, 26 men and 28 women, gave mean values of 130 ± 5.2 and 330 ± 4.9 $\mu\text{g.}$ per 100 ml. for serum Fe and total Fe-binding capacity, respectively. At parturition the mean values for 21 mothers were 98 ± 6.7 and 470 ± 15.3 $\mu\text{g.}$ and for cord samples from their 23 infants 173 ± 6.9 and 259 ± 10.5 $\mu\text{g.}$ per 100 ml. serum, respectively, for serum Fe and total Fe-binding capacity; the lower value of the latter for the infant is associated with active storage of Fe and the higher for the mother with mobilisation of Fe from the depots.

Between birth and 6 months serum Fe fell significantly from 173 ± 6.9 $\mu\text{g.}$ to 78 ± 6.1 $\mu\text{g.}$ per 100 ml. and remained at nearly this value until 3 years, after which it rose rapidly to almost adult level. Fe-binding capacity also fell during the first 2 months from 259 ± 10.5 to 212 ± 6.6 $\mu\text{g.}$, but between then and 12 months it rose to 394 ± 13.4 $\mu\text{g.}$ and then fell slowly to adult level. Serum Fe attained adult value sooner than Fe-binding capacity did. It is concluded that in infants and children the level of total Fe-binding capacity may indicate the general direction of movement of Fe between storage and mobilisation.

D. Harvey.

613

GERRITSEN, T. and WALKER, A. R. P. **Serum iron and iron-binding capacity in the Bantu.** *S. African Med. J.*, 1953, **27**, 577-581. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

Serum Fe was estimated in blood from 15 Europeans and 185 Bantu from East, Central or South Africa; in 171 samples total Fe-binding capacity was also measured. For the Europeans the mean value for Fe was 113 ± 31 $\mu\text{g.}$ per 100 ml. serum, and for the Bantu, grouped according to geographical origin, the means ranged from 98 ± 46 and 100 ± 62 for N. Transvaal and Pondoland to 360 ± 124 $\mu\text{g.}$ for Nyasaland. For total Fe-binding capacity the European mean was 335 ± 42 $\mu\text{g.}$ per 100 ml. and the Bantu means were from 309 ± 48 for Basutoland to 591 ± 142 $\mu\text{g.}$

for Nyasaland. Percentage of Fe saturation was from 26 ± 13 for N. Transvaal to 60 ± 16 for Nyasaland, the European mean being 34 ± 7 . In none was 100 per cent. saturation noted. In general Hb levels were high. Among the Pondos and N. Transvaal Bantu some very low serum Fe values, between 15 and 40 $\mu\text{g.}$, were obtained, and these in the presence of normal or even high Hb.

614

MUKHERJEE, C. and MUKHERJEE, S. K. **Studies in iron metabolism in anaemias in pregnancy.** 1. Serum iron. *J. Indian Med. Assoc.*, 1953, 22, 345-351. [Eden Hosp. Women, Med. Coll., Calcutta.]

In a study with 196 women it was shown that during normal pregnancy serum Fe decreased steadily from normal non-pregnant values of about 118 $\mu\text{g.}$ during the early weeks to a mean value which, at term, was about 74 $\mu\text{g.}$ per 100 ml. In pregnancy complicated with either microcytic or macrocytic anaemia the fall was greater, the mean value for the combined series during the last trimester being 51.7 $\mu\text{g.}$ per 100 ml. Blood volume estimations in some of the patients showed that there was a slight rise in total serum Fe in the early weeks of pregnancy, which was followed by a fall to below normal as pregnancy proceeded. The administration of HCl with meals increased Fe absorption and serum Fe during pregnancy; the occurrence of diarrhoea had the opposite effect. Serum Fe in both normal and abnormal pregnancy fell rapidly when a diet almost free from Fe was given. From these findings it is concluded that in women in Calcutta there is a depletion of the Fe reserves of the body during pregnancy.—L. Wills.

CLEGG, R. E. and HEIN, R. E. **P^{32} distribution in the serum proteins of the chicken.** *Science*, 1953, 117, 714-715. [Kansas State Coll., Manhattan.]

Eight-week-old chickens were given ^{32}P by mouth and half received an injection of diethylstilboestrol. Serum was taken from the blood of these birds and from laying hens which had eaten ^{32}P .

Electrophoretic component 1 was present and had a high activity in oestrogen-treated birds and laying birds, but was absent from non-laying birds which were not treated with oestrogen. Component 5 was present in the sera of all birds but was increased and had a greater activity in laying and oestrogen-treated birds than in non-laying and untreated birds.—R. Hill.

AMATRUDA, T. T. (Jr.) and WELT, L. G. **Secretion of electrolytes in thermal sweat.** *J. Appl. Physiol.*, 1953, 5, 759-772. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Sweating was studied in 46 experiments on 19 subjects. Samples were collected in a plastic sleeve sealed to the arm. There was great individual variation in concentrations of urea and electrolytes. There was some direct correlation between the concentrations of Na and Cl in sweat and the rate of sweating or the rise of rectal temperature, and some inverse correlation between the concentrations of Na and NH_3 in sweat, and the concentration of K and total volume of sweat lost. Intravenous infusions of isotonic, hypertonic or hypotonic fluids before exposure to heat almost always prolonged the latent period before sweating began. Hypotonicity tended to increase the rate of sweating and hypertonicity to decrease it. Acidosis produced by ingestion of NH_4Cl decreased the length of latent period, but alkalosis was without effect. A constant relation appeared between Na and Cl in sweat and extracellular fluid. The validity of analysis of thermal sweat as a diagnostic or research tool is questioned.—D. Duncan.

BERENSON, G. S. and BURCH, G. E. **A study of the sodium, potassium and chloride contents of thermal sweat of man collected from small isolated areas of skin.** *J. Lab. Clin. Med.*, 1953, 42, 58-77. [Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

619

AHLMAN, K. L., ERÄNKÖ, O., KARVONEN, M. J. and LEPPÄNEN, V. **Mineral composition of thermal sweat in healthy persons.** *J. Clin. Endocrinol.*, 1953, 13, 773-782. [Dept. Physiol., Inst. Occupat. Health, Helsinki.]

Samples of thermal sweat were collected from 67 men in different degrees of physical training, of whom 31 were champion lumbermen, 19 were soldiers and regarded as intermediate and 17 had sedentary occupations; 69 women, nurses or students, also provided samples. Mean values for Na and Cl for men in the different groups were similar, but for Na a sex difference appeared, the value for women being higher than that for men.

N.A. and R., January 1954

For K the sex difference in the same direction was even more significant. In both sexes the positive correlation between Na and Cl was linear and highly significant, $r = 0.977 \pm 0.0039$ for men and 0.913 ± 0.020 for women, but, owing to a higher Na : Cl ratio in women, the equations of the regression lines differed for the sexes.

Because of the high correlation of Na with Cl the simple titrimetric estimation of Cl is considered a satisfactory measure of adrenocortical activity, and the results indicate that, although functional capacity of the adrenal cortex in man may be of importance in relation to his physical fitness, the level of activity of the adrenals while the subject is at rest is unaffected by his physical condition. No satisfactory explanation of the sex differences could be advanced.—D. Duncan.

620

ERÄNKÖ, O. **Effect of heavy muscular work on the mineral composition of thermal sweat.** *Sport Med.*, 1953, 64-68. [Inst. Occupational Health, Helsinki.]

The results obtained from athletes (Abst. 540, Vol. 23) were compared with those from 135 other persons of different degrees of fitness. There was no significant difference in composition of thermal sweat at rest. Women had a significantly higher K concentration and Na : Cl ratio than men. Na values could be calculated with high accuracy from the easily estimated Cl values.—D. Duncan.

FORBES, R. M., COOPER, A. R. and MITCHELL, H. H. **The composition of the adult human body as determined by chemical analysis.** *J. Biol. Chem.*, 1953, 203, 359-366. [Div. Animal Nutrit., Urbana, Ill.]

The subject was a white male 46 years of age and, according to Edwards's nomogram (*Amer. J. Hyg.*, 1942, 35, 307), 23 per cent. below the average weight for his age and height. The whole body contained water 55.13, ether extract 19.44, crude protein 18.62, ash 5.43, Ca 1.907 and P 0.925 per cent. The fat-free body contained water 69.38, crude protein 23.43, ash 6.83, Ca 2.40 and P 1.164 per cent. The contents of tissues and organs are also given.

The water and fat contents were within the ranges of values estimated by indirect measure-

ments on living subjects. The Ca : P ratio of the whole body was about 2 : 1.—D. Duncan.

625

IVERSEN, K., VIDEBAEK, A. and KIRK, J. E. **Casual skin lipid levels in individuals of various ages.** *J. Gerontol.*, 1953, 8, 312-317. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

Lipid material was extracted with ether from an area of 10 sq. cm. on the forehead and from three areas of 2 sq. cm. on the back of the hands of 72 men and 72 women between the ages of 13 and 90 years.

No significant correlation was observed between age and the amount of epidermal lipid ; the mean lipid value observed for the forehead, in mg. per sq. cm., was 0.239 in men and 0.205 in women ; the corresponding figures for the back of the hand were 0.072 and 0.080.—G. A. Garton.

626

KRAYBILL, H. F., GOODE, E. R., ROBERTSON, R. S. B. and SLOANE, H. S. **In vivo measurement of body fat and body water in swine.** *J. Appl. Physiol.*, 1953, 6, 27-32. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Data were obtained on sp. gr., body fat and water content and thickness of back fat of 24 pigs aged 90 to 466 days, by methods applied either to the intact animals or to their carcasses. The mean values, with standard deviations and ranges, were sp. gr. 1.016 ± 0.02 (0.990 to 1.057) ; body fat, antipyrine method 36.7 ± 0.10 (12.0 to 49.9), sp. gr. method 40.8 ± 0.09 (19.9 to 54.5), analysis 38.4 ± 0.09 (17.8 to 53.1) per cent. ; body water, antipyrine method 46.8 ± 0.07 (36.7 to 64.5), sp. gr. method 44.1 ± 0.07 (33.8 to 59.6) per cent. ; thickness of back fat, 34.9 ± 8.09 (17.0 to 47.2) mm.

From the relations between these and from consideration of the results of other workers theoretical equations were developed to permit

calculation of body water and fat percentages:

$$\text{Body water} = 100 \left(4.400 - \frac{4.021}{\text{sp. gr.}} \right) \text{ per cent.,}$$

$$\text{and Body fat} = 100 \left(\frac{5.405}{\text{sp. gr.}} - 4.914 \right) \text{ per cent.,}$$

where sp. gr. is the body specific gravity of the eviscerated animal.—D. Harvey.

WINTER, G. and NUNN, W. **The composition of the blubber fat of crabeater seal.** *J. Sci. Food Agric.*, 1953, **4**, 439–442. [Defence Res. Labs., Dept. Supply, Melbourne.]

Blubber fat was extracted with acetone and ether from the belly of a crab-eater seal (*Lobodon carcinophagus*). The methyl esters of the component fatty acids derived by methanolysis of the fat were separated into groups of differing unsaturation by low-temperature crystallisation from acetone. Each group of esters was fractionally distilled *in vacuo*, with a spinning-band column. From analysis of each fraction the whole fat was estimated to have the following percentage composition by weight: myristic acid 4.7, palmitic acid 10.1, stearic acid 2.1, unsaturated C₁₄ 3.2, unsaturated C₁₆ 19.8, unsaturated C₁₈ 30.3, unsaturated C₂₀ 19.2 and unsaturated C₂₂ acids 10.6.

WINTER, G. and NUNN, W. **The component fatty acids of elephant-seal oil: variations and relationship to blubber fats of other seals.** *J. Sci. Food Agric.*, 1953, **4**, 442–448. [Defence Res. Labs., Dept. Supply, Melbourne.]

Blubber fat was extracted from male and female elephant seals ranging in age from pups to adults taken at different seasons at Heard Island and Macquarie Island. The fatty acid composition of the fats was estimated as described in the preceding abstract.

There was little correlation between fat composition and size, age or sex of the animal. The following fatty acids were identified: lauric 0 to 0.4, myristic 1.1 to 6.3, palmitic 8.2 to 14.0, stearic 2.1 to 4.6, arachidic 0 to 0.7, behenic 0 to 0.2, unsaturated C₁₄ 0.6 to 2.3, unsaturated C₁₆ 8.2 to 17.8, unsaturated C₁₈ 32.9 to 44.4, unsaturated C₂₀ 11.7 to 25.3, unsaturated C₂₂ 5.9 to 13.2 and unsaturated C₂₄ 0 to 3.1 molecules per cent.—G. A. Garton.

629

HARRISON, M. F. **Effect of starvation on the composition of the liver cell.** *Biochem. J.*, 1953, **55**, 204–211. [Dept. Exp. Med., Univ. Cambridge.]

Changes in the liver were studied in rats fasted for 1, 2, 4 or 6 days, with access to water. Complete

data are presented as the mean values for 7 animals for liver water, protein, glycogen, neutral lipids, phospholipins, nucleic acids, total and inorganic Fe, Cu, Zn, K, Na, Cl and P.

Reduction in size of liver appeared to be the result of loss of cytoplasmic, and not of nuclear, material. In 24 hr. glycogen almost disappeared from the liver cells of both sexes, but later a sex difference arose, since it increased somewhat in the male and not in the female. Neutral lipid also differed at the end of the fast, being greater in the liver cells of females than of males. Throughout the fast there was loss of protein and in the last 2 days this also was greater in the female than in the male. Fe, Cu and Zn remained unchanged. Losses of water and K ran almost parallel with that of protein throughout the fast.—D. Harvey.

COLE, P. G., LATHE, G. H. and RUTHVEN, C. R. J. **The application of countercurrent methods to the fractionation of lipid material from human placenta.** *Biochem. J.*, 1953, **55**, 17–23.

N.A. and R., January 1954

[Bernhard Baron Mem. Res. Labs., Queen Charlotte's Maternity Hosp., London.]

With a solvent system of carbon tetrachloride, methanol and water, the lipids of human placenta were fractionated by counter-current distribution. The fractions were analysed for cholesterol, iodine value and N and P content of non-cholesterol material and, after hydrolysis, for bases and phosphates by paper chromatography.

Several fractions contained ethanolamine, choline and serine; glutamic acid was widely distributed, suggesting some general relationship between this amino-acid and placental lipids. The N and P contents of the fractions were not consistent with the occurrence of the usual phospholipids, and it is suggested that the high P and low N values found may be due to phosphate-containing lipids of a new type. The composition of placental lipids is compared with the composition of brain lipids distributed by the same counter-current technique.

CREMER, H. D., BÜTTNER, W., DITTMANN, G. and VOELKER, W. Ernährungsfaktoren bei Zahn- und Knochenbildung. 2. Der Mineralgehalt der Zähne bei Carieskost. [Diet components in the formation of teeth and bones. 2. Minerals in teeth with a caries-producing diet.] *Biochem. Ztschr.*, 1953, **324**, 83-88. [Physiol. Chem. Inst., Univ. Mainz.]

For part 1, see Abst. 899, Vol. 22.

A study was made of minerals in the teeth of the second, third and fourth generations of rats kept on a caries-producing diet consisting of casein 24, cane sugar 63, olive oil 5, liver 4, and Shaw's salt

mixture 4 per cent., with vitamin B₁ 2.5, riboflavin 1, pyridoxine 1, nicotinic acid 10, Ca pantothenate 1.5 and tocopheryl acetate 2.5 mg., vitamin A 500 and vitamin D 10 I.U. per 100 g. Controls had casein 50, cane sugar 14, lard 20, and olive oil 8 per cent., otherwise their diet was the same as that of the experimental rats. Rats were killed either at 17 to 21 days of age when the molars were about to erupt, or at 10 to 15 months. The upper teeth were cleaned and dissolved in 2 N HCl and Ca, P, F and Mg were estimated.

Contrary to the results of Hartles (Abst. 838, Vol. 21), the Ca and P contents of the teeth of experimental and control rats were similar. F content fluctuated between 6 and 28 mg. per cent. but a difference between the 2 groups could not be established. On the other hand, the Mg content of first molars of fourth generation rats on the caries-producing diet was only about 3/4 that of control rats. This difference was not found in the incisors.—W. M. Deans.

DUCTLESS GLANDS AND HORMONES

638

SCHABERG, A. and STRAUB, M. The adrenals in hunger cachexia. *Doc. Med. geograph. trop.*, 1953, **5**, 49-55. [Pathol. Lab., Municip. Hosps., Rotterdam.]

In 1946 post-mortem examination of 60 Indonesians with hunger cachexia, including both dry and wet forms, showed a mean bodyweight of 29 kg. compared with from 40 to 50 kg. for normal Indonesians. The blood sugar value estimated after death was extremely low in many of them. There were constant characteristic changes in the adrenal glands; they were small and flat and the yellow cortex was reduced so that the medullary zone predominated. Microscopically the cortex showed a relative broadening of the glomerular zone, the cells of which tended to be undifferentiated and had in places penetrated the capsule. The fascicular zone was very narrow; the cells

were poor in lipids and strongly eosinophilic. The reticular zone was relatively large and showed central accumulations of lipofuscin.

The picture of complete exhaustion of the adrenal glands seen in the Indonesian patient differs greatly from that in similar cases in Europe, where there is hyperplasia of the cortex with depletion of lipid. It is suggested that the apparently contradictory findings can be explained in accordance with Selye's picture of the response of the adrenal glands to stress. The changes in the Europeans occurred in persons previously well fed and were of the "resistant phase" type, whereas in the malnourished Indonesians the glands were in the "resistant phase" before starvation occurred and showed changes characteristic of the "exhaustion phase" when hunger cachexia developed.—L. Wills.

BURNS, T. W., ENGEL, F. L., VIAU, A., SCOTT, J. L. (Jr.), HOLLINGSWORTH, D. R. and WERK, E. (with ROBERTSON, E.) **Studies on the interdependent effects of stress and the adrenal cortex on carbohydrate metabolism in man.** *J. Clin. Invest.*, 1953, **32**, 781-791. [Dept. Med., Duke Univ., Durham, N.C.]

Glucose, glucose-insulin and insulin tolerance tests were made on 143 normal medical students and 53 patients, 4 with severe neuroses and the remainder with organic disease. Except in a diet control experiment, all were on normal diets.

In a control experiment ingestion of 200 or 400 mg. cortisone acetate by groups of 10 normal subjects produced a significant and sustained increase in fasting blood sugar during the period from 4 to 7 hr. afterwards. In glucose tolerance tests on normal subjects those who received cortisone showed impaired tolerance, but their glucose-insulin or insulin tolerance was not affected. Restriction of food intake in normal subjects did not affect these results. In ill subjects cortisone produced a strikingly greater impairment of glucose and glucose-insulin tolerance than did illness alone. The glucose-insulin test, with or without cortisone, showed the greatest difference between normal and ill subjects. Cortisone-treated patients exhibited only slightly greater insulin resistance in this test than untreated patients, but all showed much greater resistance than normal subjects receiving cortisone over a short or long period.

The results are fully discussed with reference to the concept that adrenal hormone influences the metabolic response to stress. It is considered that these responses are not direct consequences of increased adrenal cortical secretion.—D. Duncan.

640

STERLING, R. E. and LONGWELL, B. B. **The effect of type and quantity of food intake on the response of the adrenal gland to cold exposure.** *Endocrinology*, 1953, **53**, 106-113. [Dept. Biochem., Univ. Colorado Sch. Med., Denver.]

Estimations of adrenal cholesterol and liver glycogen were used to study adrenal cortical activity in response to stress in 4 experiments on adult male rats. In the first experiment the rats were fed only at night, on Purina chow. Before the experiment, groups 1 and 3 were fed as usual, groups 2 and 4 were fasted for 24 hr., and groups 5 and 6 received half and one-quarter, respectively, of their usual food consumption. Groups 3, 4, 5 and 6 were exposed to a temperature of 3° to 5° C. for 4 hr., and then all animals were anaesthetised with Nembutal before removal of adrenals and livers for analysis. Group 1, controls, had adrenal cholesterol contents of 3.7 ± 0.21 per cent., and the mean liver

glycogen content was 3.60 per cent. Fasting alone had no effect on adrenal cholesterol. Exposure to cold without fasting reduced adrenal cholesterol to 3.0 ± 0.18 and liver glycogen to 2.7 per cent. In groups 4, 5 and 6, partly fed rats showed lower adrenal cholesterol values than fasted rats, namely, 2.3 ± 0.25 , 2.0 ± 0.14 and 2.0 ± 0.12 per cent., respectively. There was no direct correlation between absolute glycogen values and adrenal response in individual animals.

In 2 other experiments groups of rats received high-fat, high-carbohydrate or high-protein diets for 7 days before exposure. In the first of these experiments the diets were given to appetite, and in the second energy intake was restricted to that of the high-protein group, about three-quarters of the voluntary intake of the high-fat and high-carbohydrate groups. In a final experiment this energy intake was allowed to rats on Purina chow.

With unrestricted food intake high-fat and high-carbohydrate diets afforded more protection against adrenal cholesterol depletion than did high-protein or stock diets. Food restriction associated with high fat and carbohydrate intakes led to almost normal liver glycogen values in non-stressed groups, 3.1 and 4.2 per cent., respectively. Cholesterol values were high, 5.4 ± 0.27 and 5.1 ± 0.36 per cent., and exposure to cold had little effect, 5.0 ± 0.36 and 5.1 ± 0.41 per cent., respectively. Exposure to cold after the high-protein diet reduced adrenal cholesterol from normal values to 2.8 ± 0.29 per cent.

It was concluded that fasted animals with depleted liver glycogen responded more readily to stress, but results do not suggest that liver glycogen was the only condition modifying the adrenal response; the unexpected effect of high protein intake was thought to indicate a more complex phenomenon.—D. Duncan.

MALMROS, H. and SWAHN, B. **Lipid metabolism in myxedema.** *Acta med. scand.*, 1953, **145**, 361-369. [Dept. Med., Univ. Hosp., Lund.]

In a study of blood lipids of 2 men and 11 women with myxoedema, the amounts of total serum lipid, cholesterol and phospholipins were found to be abnormally high. Administration of *l*-thyroxine brought about a decline to normal plasma levels. It is suggested that serum lipid analysis is often more reliable than measurement of B.M.R. in the assessment of thyroid function.—G. A. Garton.

1. Some aspects of growth and metabolism were studied in 4 infant macaque monkeys from birth to 140 days. Feeding was unrestricted. N, Ca and P balances were estimated during two or three 72-hr. periods. The diet contained carbohydrate 60 to 65, protein 12 to 15 and fat 20 to 25 per cent. All the animals gained about 10 ± 1 g. per kg. daily during the first 30 days and then the average weight gain declined to 5 ± 1 g. per kg. daily. The food intake declined from 375 to 200 Cal. per kg. daily at 140 days. N retention paralleled growth and between 40 and 140 days 104 ± 4 mg. N per g. weight gain was retained. Ca and P retentions were more variable, but the ratio of Ca to P retained was constant. Ca retention was on the average 25 mg. per g. weight gain after 75 days.

2. Growth and metabolic changes were studied over a 4-month period in 2 young monkeys whose thyroid glands were ablated after birth and in 2 older animals so treated at 4 and 5 months. Ablation was by intraperitoneal injection of ^{131}I in isotonic carrier-free solution containing about 1 mC. per ml. Serum butyl-extractable I in normal young monkeys ranged from 4 to 8 μg . per 100 ml. Thirty or more days after the final dose of ^{131}I this value ranged from 0 to 1 μg . per 100 ml. in all 4 monkeys. Parathyroid integrity was confirmed by periodic Ca and inorganic P analyses on sera.

Between 15 and 20 days after thyroid ablation in the 2 young monkeys and after about 35 days in the 2 older monkeys striking changes developed, resulting in a clinical picture similar to that of the athyroid human infant, i.e., macroglossia, generalised myxoedema, sluggish movements, increase of somnolence and a drop in body temperature when placed in a cooler room. Growth stopped and the animals assumed a crouching posture, skin

became thick, hair coarse and scanty, eruption of teeth was delayed and there was enlargement of the palatoglossal and palatopharyngeal arches in the young monkeys. Growth of the long bones was delayed, as well as maturation of the whole skeleton. There was enlargement of the sella and a flattening of the basiocciput.

Voluntary energy intake dropped by half to 100 ± 10 Cal. per kg. daily. N, Ca and P retentions were greatly reduced. Urinary creatine and creatinine were on the average about half normal.

LAMBERG, B. A. **Radio-active phosphorus as indicator in a chick assay of thyrotropic hormone.** *Acta med. scand.*, 1953, **145**, Suppl. 279, pp. 79. [Inst. Pharmacol., Univ. Helsinki.]

It was found by Borell (Title 647, Vol. 16) that in response to thyrotropic hormone the total P content of the guinea pig's thyroid increased with the height of the epithelial cells, and later (Borell and Holmgren, *Acta endocrinol.*, 1949, **3**, 331) that when ^{32}P was given the increased activity was in direct proportion to the increased cell height.

The experimental animals were 1379 chickens from 1 to 3 days old, kept in a controlled environment and fed from the second day on a commercial chick ration. The thyrotropic substance (TSH) used was a standard preparation, Ambion, injected subcutaneously. ^{32}P was also given subcutaneously as 100 mg. sodium phosphate containing 2 to 12 μC . tracer. The estimation of radio-activity in tissue samples and the histological and statistical methods are discussed.

TSH increased the uptake of ^{32}P by the thyroid, the maximum uptake occurring 8 hr. after TSH injection and being maintained until 12 hr. The effect of TSH on the thyroid epithelium reached its maximum at 4 hr. and was maintained at least up to 8 hr. For assay of TSH it was therefore given 8 hr., and ^{32}P 60 min., before the chickens were killed.

A linear log dose response relation was found to be valid within the range from about 0.005 to 0.05 or 0.1 Junkmann-Schoeller unit. The reaction appeared to be specific for TSH, and the uptake of ^{32}P was at least as specific an end reaction as the increase in percentage of epithelium.

There were fairly large variations in response with different broods of chickens, and a standard

curve could not be developed, so unknown TSH preparations must be tested against a standard preparation. Chickens aged 1, 2 and 3 days were equally responsive. For a 4-point assay the amount of unknown substance required is at least $n \times 0.025$ unit, where n is the number of animals per point. It is suggested that the method may be used for titration of TSH in body fluids.

DAVIES, B. M. A. and GORDON, A. H. **The effect of parathyroid hormone on phosphate excretion in the rat.** *J. Endocrinol.*, 1953, 9, 292-300. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

Rats with parathyroids removed were given injections of parathyroid hormone in different amounts. Decreases of serum phosphate and increases of urine phosphate were related to the quantity of hormone injected, though the increase in response became less when more than about 3 units were given. The response in different animals to a particular quantity of hormone varied with the initial phosphate content of serum or urine.

The individual variations in response were too great for this technique to be useful in its present form as a method of estimating the parathyroid hormone.—R. Hill.

CAMPBELL, J., HAUSLER, H. R., MUNROE, J. S. and DAVIDSON, I. W. F. **Effects of growth hormone on dogs.** *Endocrinology*, 1953, 53, 134-162. [Dept. Physiol., Univ. Toronto.]

Four adult dogs received, after a preliminary control period, 2 daily injections of bovine growth hormone for 7 days, in amounts sufficient to produce diabetes within about 3 days. One dog died in diabetic coma, but the other 3 were allowed to recover for 30 days and were then given a second series of injections for 6 to 8 days before being killed. Control dogs received injections of bovine plasma albumin. The diet consisted of ground horse muscle 300 g., Purina checkers 100 g. and sucrose 40 g., in 2 meals, but the experimental dogs received only half this amount after the end of the first week of injections. Blood volumes were estimated by the T 1824 method and blood and urine samples were collected for analysis.

The growth hormone preparation in the first period, in doses of 3.5 mg. per kg. bodyweight

daily, produced pronounced diabetes, with blood sugar values above 300 mg. per 100 ml., glycosuria, polyuria, polydipsia, ketonuria and lipaemia. The dogs became lethargic, respiratory rate increased, with vomiting, loss of appetite, dehydration and tarry stools suggesting haemorrhage from the upper alimentary tract. The 3 survivors recovered within 4 to 6 days after the injections ceased. In the second period the dose of hormone was reduced to 2 mg. per kg. daily and diabetes occurred in 2 dogs.

Growth hormone increased the red blood cell sedimentation rate and decreased the haematocrit, Hb concentration and red cell count. Plasma volume increased by 10 to 15 per cent. above control values; the reductions in cell values were due to dilution by increased plasma volume. Total plasma protein was increased by the increased volume; the effect on plasma albumin was not definite, but globulin was increased and the albumin:globulin ratio was low. Fibrinogen was considerably increased. Clotting time and prothrombin time showed rapid and progressive decreases. Leucocyte counts increased, especially those of neutrophil granulocytes.

At the end of the second injection period the livers of the 3 dogs given growth hormone had an average weight more than twice that of 5 controls. Fat-free solids, water and fat in liver were all increased, especially fat. Little insulin could be obtained from the pancreas. The significance of all these results is discussed.—D. Duncan.

CAHN, T. and HOUGET, J. **Influence de l'insuline sur la production calorifique du lapin. [Effect of insulin on heat production in the rabbit.]** *J. Physiol., Paris*, 1953, 45, 429-441. [Lab. Physiol., Inst. Biol. Physico-Chim., Paris.]

Energy exchange was studied in rabbits over 48 hr., each day being divided into a 7- and a 17-hr. period. Each rabbit was subjected to a control

N.A. and R., January 1954

experiment and, 4 to 8 days later, to an experiment in the course of which insulin was injected.

Whether the rabbits were fasted or fed, insulin had no effect upon the 24-hr. energy exchange; there was sometimes an increase in output during the first 7 hr., but this was always compensated later. There was no regular variation in R.Q., and insulin is not thought to favour combustion of sugars.—D. Duncan.

EBBEL, FONTAINE, R. and MANDEL, P. Action de la folliculine sur le bilan du Ca au cours d'un régime couvrant le minimum des besoins calciques. [Effect of folliculin on calcium balance

on a diet supplying minimum calcium requirement.] *C.R. Soc. Biol.*, 1953, 147, 508-511.

When 9 adult female rats receiving a diet containing the minimum Ca requirement were given daily injections of folliculin retention of Ca and P was much increased. Ca equilibrium was controlled during a pre-period of 15 days and the experimental period lasted 12 days, estimations being made on the combined excreta of 3 days. Faecal excretion of Ca decreased by 42 per cent. or 2.01 mg. and of P by 36 per cent. or 2.97 mg. daily. Urinary excretion of P diminished by about 10 per cent. in 8 of 9 rats; urinary Ca showed in 7 a slight increase, insignificant relative to the decrease of intestinal excretion.—M. B. Richards.

Data exist whereby B.M.R. can be assessed from body size, sex, age, race and climate, but little is known of the effect of these on metabolism during muscular exercise. An investigation was made of the energy expenditure of 50 Europeans and Asiatics of both sexes when performing 2 standard exercises, stair-climbing and walking. The data

Vol. 24, No. 1

are analysed statistically to show that bodyweight can be used to predict energy expenditure closely and that use of height, age, sex, race or resting metabolism does not give additional information on energy expenditure. Further, in climbing stairs, where a large proportion of the energy expended is used to raise the body, the metabolic cost is directly proportional to bodyweight.—A. W. Boyne.

- ROBINSON, K. W. and KLEMM, G. H. **A study of heat tolerance of grade Australian Illawarra Shorthorn cows during early lactation.** *Austral. J. Agric. Res.*, 1953, **4**, 224-234. [Sir William Macgregor Sch. Physiol., Univ. Queensland, Brisbane.]

The reactions were studied of four 3-year-old grade Australian Illawarra Shorthorn cows, 3 weeks calved, exposed for 7 hr. twice weekly for 6 weeks to different combinations of dry-bulb temperatures ranging from 86° to 108.5° F. and absolute humidity from 8 to 16 g. moisture per c. ft.

Temperatures up to 95° F. appeared not to affect the animals, but higher temperatures caused a marked rise of body temperature. Pulse rate was unaffected throughout. At constant humidity of 12 g. per c. ft. and at increasing air temperatures the cows appeared contented up to 104° F., and water was drunk when offered. At air temperature above 104° F. rumination ceased, water was not taken, and panting occurred; at 105° F. sweating occurred freely, and at 106° F. all animals showed marked distress, and above 107° F. signs of heat stroke. A rise of humidity caused stress at lower dry-bulb temperatures. On comparing the reactions of the Shorthorns with those of 4 Jersey cows of similar age and lactation it was found that the Jerseys had a much greater heat tolerance.—E. L. B. Haskew.

The body temperature of the elk varies with the time of day and particularly with the season of the year; the temperature variations are directly related to the temperature of the surroundings. In winter the elk is capable of maintaining its normal functions at a lower body temperature than in the summer. During hard frost movement is reduced to a minimum and the elk usually lies down. In the summer the sun's heat leads to a rapid rise in body temperature which reduces the

elk's working capacity. The elk must be trained before it is of much use for work; nervous types are not good for training, since they are easily excited; this leads to rise of body temperature and reduces the working efficiency. (From auth summary.)—W. Hughes.

- HORVATH, S. M., HUTT, B. K., SPURR, G. B. and STEVENS, G. E. **Some metabolic responses of dogs having low body temperature.** *Science*, 1953, **118**, 100-101. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

After preliminary anaesthetisation with Nembutal to prevent shivering it was possible to expose dogs to room temperatures low enough to reduce the rectal temperature and to maintain it at about $24^{\circ} \pm 1^{\circ}$ C. for as long as 28 hr. with subsequent recovery. Metabolic data are given for 2 of these dogs and are similar for both.

In dog A the rectal temperature was at $23.6^{\circ} \pm 1.5^{\circ}$ C. for 28 hr. The mean body temperature was 22.7° C. Heart rate fell from 84 to 36 beats per min., O_2 consumption from 96 to 17 ml. per min., respiratory rate from 8 to 2 per min. Heat production fell from 34.7 to 6.2 Cal. per sq. m. per hr., and averaged 11.3 Cal. per sq. m. per hr. for the last 27 hr. of exposure.

In 18 experiments on 11 dogs the reduction in heat production and the fall in rectal temperature were exponentially related, and application of van't Hoff's law to warm-blooded organisms within this temperature range would appear to be valid.—D. Duncan.

667

- MAYER, J. and GREENBERG, R. M. **Hyperthermia in hypothalamic hyperphagia.** *Amer. J. Physiol.*, 1953, **173**, 523-525. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Production of hypothalamic lesions and subsequent increase of appetite are described in Abst. 746, Vol. 23. Rats weighing 350 to 550 g. were considered to be overeating. Such animals had colonic temperatures of $37.45 \pm 0.33^{\circ}$ C., compared with intact controls, $36.78 \pm 0.3^{\circ}$ C. Fasting for 2 or 6 hr. did not eliminate the difference. In rats recently operated on which were not obese the temperature was consistently high, even when they were not gaining weight. Exposure to heat, 40.0° C., or to cold, 3.5° C., showed that affected rats had no gross impairment of heat regulation. The significance of the results is discussed.

- HALBERG, F. and VISSCHER, M. B. **A difference between the effects of dietary calorie restriction on the estrous cycle and on the 24-hour adrenal**

N.A. and R., January 1954

cortical cycle in rodents. *Endocrinology*, 1952, **51**, 329-335. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

Female C₃H mice were singly housed from weaning in metal cages with temperature and illumination controlled. The control group of 28 mice each received 2.66 g. food daily and 17 mice in the restricted group 1.51 g. daily, the reduction being made in carbohydrates and fats only. At 6 months of age the average weight of control mice was 29 g. and of restricted mice 18 g. The amplitude of the diurnal eosinophil rhythm, when tested statistically, was slightly greater in the restricted than in the control group.

The uteri of the control group, at 195.6 ± 23 per 100,000 of bodyweight, were heavier than those of the restricted group at 39.8 ± 1.4 . The adrenal glands did not differ significantly in weight.

It is concluded that the 24-hr. adrenal cortical cycle is not suppressed in conditions known to suppress the oestrous cycle.—A. Iggo.

HUTCHINSON, J. C. D. and SYKES, A. H. **Physiological acclimatization of fowls to a hot humid environment.** *J. Agric. Sci.*, 1953, **43**, 294-322. [Agric. Res. Coun. Poultry Centre, King's Bldgs., Edinburgh.]

In tests with inbred Brown Leghorns, 3 cocks and 3 hens in each group, acclimatisation to tropical climates was investigated. The birds were maintained on an adequate diet and exposed to temperatures of 99°, 102° or 104° F. for 4 hr. daily or continuously for 21 days, without ill

effect on egg production, feed intake or liveweight. Short daily periods in the hot climate increased heat tolerance as indicated by rectal temperature, 102° F. air temperature producing the same heat stress in acclimatised birds as 99° F. in unacclimatised. Continuous residence in the hot climate further improved heat tolerance. Cocks were more tolerant than hens. Evaporative loss was reduced by acclimatisation, but respiratory rate was not significantly affected. In severe heat stress, when rectal temperature was about 110° F., there was an increase in heart rate, less when the birds had been acclimatised.—T. D. Bell.

670

HUTCHINSON, J. C. D. **Effect of hot climates on egg weight.** *Poultry Sci.*, 1953, **32**, 692-696. [Poultry Res. Centre, Kings Bldgs., Edinburgh.]

Two groups of 3 pullets were exposed for up to 4 hr. daily on 6 days a week, for about 6 weeks, in a climatic chamber. In the first 24 exposures the temperature was 99° F. and humidity 28 mm. Hg vapour pressure. In the last 5 or 6 exposures the temperature was higher. Between exposures the birds were kept in an environment at or below 60° F. After this intermittent acclimatisation they were kept continuously at about 85° F. for 3 weeks and then at 90° F. for 4 weeks.

Egg weight was reduced during the intermittent exposures to heat, but increased, though not to control level, in continuous exposure at somewhat lower temperatures.—M. J. Head.

WARD, O. C. **Blood sugar studies on premature babies.** *Arch. Dis. Childhood*, 1953, **28**, 194-197. [Dept. Child Health, Alder Hey Child. Hosp., Liverpool.]

In 21 infants who weighed $5\frac{1}{2}$ lb. (2500 g.) or less at birth, blood sugar was estimated at 6-hr. intervals for the first 48 hr. Only 4 babies received any feed during this time. The cord blood sugar ranged from 40 to 140 mg. [presumably per 100 ml., although this is not stated], mean 66, and the postnatal levels from 16 to 90 mg. per 100 ml. The mean value on the first day of life was 44 and on the second day 45. As others have found, no relation between blood sugar and birthweight could be demonstrated.—M. S. Fraser.

ADDISON, V. E., TUTTLE, W. W., DAUM, K. and LARSEN, R. **Effect of amount and type of protein in breakfasts on blood sugar levels.**

J. Amer. Dietetic Assoc., 1953, **29**, 674-677. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

Earlier work (Abst. 4542, Vol. 23) had shown that a breakfast containing 25 g. protein would maintain blood sugar for $3\frac{1}{2}$ hr. at a level above fasting. The present studies were on 14 normal women who ate each of 2 breakfasts containing 15 g. protein, in one mainly of animal and in the other mainly of vegetable origin. Each breakfast maintained blood sugar above fasting level for about 2 hr., after which it fell below this level, but not by significant amounts. It is concluded that, irrespective of its source, 15 g. protein is the amount required in a breakfast to maintain blood sugar during late morning hours at a level not significantly different from fasting.—D. Harvey.

ALSLEV, J. Vergleichende Untersuchungen über den intermediären Galaktose- und Dextrosestoffwechsel bei Gesunden und Leberkranken. [Comparative studies of intermediary metabolism of galactose and glucose in healthy persons and patients with liver disorders.] *Ztschr. ges. exp. Med.*, 1953, **121**, 1-11. [Med. Klin., Univ. Kiel.]

After taking glucose or galactose the blood sugar curves in patients with liver cirrhosis rose higher than in normal persons and the added sugars disappeared more slowly from the circulation. Blood lactic acid and pyruvic acid rose more sharply in normal persons than in those with liver disorders, especially after galactose, reaching a peak after 60 min. and returning to normal by 210 min. In liver cirrhosis the fasting values for blood lactic acid and pyruvic acid were higher than in normal persons, but after glucose or galactose the curves rose more slowly and the rise was increased or maintained up to 210 min. Similar, but less marked, deviations were found in patients with icteric hepatitis. The results are discussed from the biochemical standpoint in relation to previous findings.—M. B. Richards.

HEIN-SEKULA, M. and SIEDEK, H. Ueber den Einfluss von ACTH und Cortison auf den Galaktosestoffwechsel. [Influence of adrenocorticotrophic hormone and cortisone on galactose metabolism.] *Wien. klin. Wochenschr.*, 1953, **65**, 572-574. [I. Med. Klin., Univ. Vienna.]

Studies were made on 30 subjects of the effects of cortisone and adrenocorticotrophic hormone on the response to intravenous injection of 20 g. galactose in the fasting state. Both hormones increased the amount of galactose excreted in the urine and decreased the concentration of it in the blood. During the first 2 hr. after the injection of galactose and either hormone there was some increase in the amounts of sugar, lactic acid and pyruvic acid in the blood. The results are discussed with reference to similar studies by the authors with fructose (*Wien. klin. Wochenschr.*, 1952, **64**, 391) and to other observations reported in the literature on the role of cortical hormones in carbohydrate metabolism.—A. M. Copping.

JORDE, W. O. Beitrag zum Laevulose- und Kreatinstoffwechsel. [The metabolism of fructose and creatine.] *Ztschr. ges. exp. Med.*, 1953, **121**, 170-180. [I. Med. Klin., Univ. Munich.]

After injections of 0.25 g. fructose per kg. body-weight, patients with hepatitis showed in the first 30 min. no significant difference from normal subjects in the total reducing power or fructose content of the blood. In normal subjects the fructose disappeared completely from the blood within 30 min., but in patients with hepatitis it persisted for between 60 and 120 min., except in one patient with cirrhosis, in whom fructose was still present after 2 hr. Blood lactic acid showed no increase in normal subjects within 15 min. after injection of fructose. Fasting blood lactic acid was low in those with liver disorders and in 2 subjects with healthy livers but much reduced bodyweight. In patients with hepatitis it showed a significant increase from its low initial value but did not reach the normal. Repeated administration of fructose tended to increase the values. Injections of creatine and creatine phosphate had no effect on blood sugar and lactic acid curves after administration of fructose.—M. B. Richards.

687

MACKLER, B. and GUEST, G. M. Effects of acidosis on the metabolism of fructose. *Amer. J. Physiol.*, 1953, **174**, 54-56. [Child. Hosp. Res. Found., Univ. Cincinnati, Ohio.]

Intravenous fructose tolerance tests on 3 dogs in the normal fasting state and in acidosis induced by continuous intravenous perfusion of ammonium chloride solutions showed that the rates of disappearance of fructose from the blood were the same. In 6 experiments on blood with fructose added *in vitro*, little or no fructose disappeared from the blood until the concentration of glucose reached a low level. Thereafter the rate of disappearance of fructose reached a maximum and then decreased logarithmically. Comparison of fructose breakdown in blood showed that the rate of fructose disappearance was slower in the acidotic than in the control sample. The results indicate that fructokinase is probably absent from blood and that acidosis inhibits the utilisation of fructose by blood cells.—M. B. Richards.

PANSINI, R. and CASAULA, A. L'effetto del carico glicidico sull'acido piruvico arterioso e venoso, alla luce del fenomeno della variabilità piruvicemica spontanea, nei soggetti sani. [The effect of giving glucose on the amount of pyruvic acid in the arterial and venous blood, in the light of the spontaneous variation in the pyruvic acid content of the blood of healthy persons.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1783-1787. [Ist. Patol. Med., Univ. Bari.]

Pyruvic acid and sugar were estimated in the blood of 17 fasting, resting subjects before and at intervals of up to 2 hr. after administration by mouth of 0.75 g. glucose per kg. bodyweight. Blood sugar increased in all subjects in both venous and arterial blood. The individual values for pyruvic acid varied widely, but were raised, usually only to a moderate extent, in the arterial blood of 13 subjects and in the venous blood of 14. The increase in the venous blood was usually the greater.—E. M. Hume.

691

ALSLEV, J. and MÖCKEL, W. Über den Einfluss der Brenztraubensäure und Milchsäure auf die Alkalireserve. [Influence of pyruvic acid and lactic acid on the alkali reserve.] *Klin. Wochenschr.*, 1953, **31**, 561-564. [Med. Klin., Univ. Kiel.]

The effect on the lactic and pyruvic acid in the blood and on the alkali reserve of giving glucose or galactose was examined in 8 healthy and 16 diabetic subjects. In normal subjects intake of glucose or galactose in the fasting state caused a slight increase in pyruvic acid and a moderate increase in lactic acid, with a decrease in the alkali reserve. The effect was more marked with galactose than with glucose, the alkali reserve being reduced by 5.7 vol. per cent. as measured by Van

Slyke's method. The effect of galactose was of the same order in diabetic subjects though the rise in lactic acid was greater and the decrease in alkali reserve was by 6.6 vol. per cent. There was no increase in acetone bodies and the fall in alkali reserve was much less than the severe depletion observed in diabetic coma.—A. M. Copping.

KRIVIT, W., POLGLASE, W. J., GUNN, F. D. and TYLER, F. H. Studies in disorders of muscle. 9. Glycogen storage disease primarily affecting skeletal muscle and clinically resembling amyotonia congenita. *Pediatrics*, 1953, **12**, 165–177. [Dept. Med., Sch. Med., Univ. Utah, Salt Lake City.] Spanish summary.

A detailed description is given of the clinical, biochemical and pathological findings in 3 siblings under the age of 2 years. The basic lesion in all three was an excessive storage of glycogen in the skeletal muscles. During life the condition could be distinguished from *amyotonia congenita* only by muscle biopsy. There was no marked enlargement of the liver, hypoglycaemia or ketosis, but muscle weakness was present and the age of onset and time of death were early. The glycogen content of the liver was much less than in the hepatomegalic type and that of the muscles much greater. Glycogen isolated from both biopsy and post-mortem material from 1 patient showed by physicochemical analysis that post-mortem glycogen breakdown occurred to some extent, in contrast to the hepatomegalic type, and that the glycogen from this patient had a low average chain length and showed excessive branching as compared with normal glycogen. There was also an increase in a low molecular weight component of muscle glycogen from the patient as compared with normal muscle glycogen.—L. Wills.

TRIBE, D. E. and GORDON, J. G. Effect of different starches on the choice of diet by rats. *Brit. J. Nutrition*, 1953, **7**, 202–207. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Four diets were used with the following basal composition: vitamin-free casein 230, glucose 330, margarine 150, salts 50, raw unground starch 400 g. and Radiostoleum 4 ml. Diet 1 contained potato starch, diet 2 rice starch, diet 3 maize starch. Diet 4 contained maize starch and was supplemented with vitamins of the B complex. Each of 4 groups of 6 young rats was offered a choice of 2 diets.

Diet 3 was consumed in larger amounts than diet 1 by all except 1 rat; all 6 rats died. Diets 2 and 3 were consumed in equal amounts; all the rats died. Diet 4 was chosen in preference to diet 1 or diet 2. The rat which preferred the potato starch to the maize starch diet was given ground potato starch after 33 days, whereupon it ceased to eat the potato starch diet until unground potato starch was restored. A rat which preferred the maize starch diet to the potato starch for 36 days changed to the potato starch diet when ground potato starch replaced unground in the optional diet.

GEIGER, E. and WICK, A. N. Nitrogen sparing effect of carbohydrate investigated by feeding of C¹⁴ labeled glucose. *Arch. exp. Pathol. Pharmacol.*, 1953, **219**, 518–527. [Dept. Pharmacol., Univ. S. California, Los Angeles.]

The amino-acid mixture used consisted of valine 1.1, leucine 1.2, isoleucine 0.75, methionine (racemic) 1.0, threonine 0.75, phenylalanine

N.A. and R., January 1954

(racemic) 1.05, tryptophan 0.3, lysine HCl 1.9, histidine HCl. H_2O 0.9, arginine HCl 0.4, $NaHCO_3$ 1.3 parts by weight. In all experiments the rats received 500 mg. of the mixture by stomach tube. The glucose used was labelled with ^{14}C and 1 g. was given in solution by stomach tube, with 100 mg. $NH_4H_2PO_4$.

In experiment 1, 12 rats received a protein-free diet for 14 days; 6 then received the amino-acid mixture and the labelled sugar solution simultaneously and 6 received the sugar 4 hr. after the amino-acids. All were killed 8 hr. after receiving the amino-acids. The distribution of ^{14}C in the carcasses was similar in both groups.

About 75 per cent. of the liver was removed in the next experiment, and the rats were given the protein-free diet for 48 hr. before administration of amino-acids and sugar, together or separately as before. ^{14}C uptake by the regenerating liver protein was higher when the substances were given together or when glucose was given first than when glucose was given later. In another experiment glucose was given alone and ^{14}C uptake by liver protein was yet higher.

^{14}C was incorporated in significant amounts into 6 liver amino-acids, in descending order arginine, alanine, glutamic acid, aspartic acid, glycine and serine. The essential amino-acids showed no ^{14}C uptake.—D. Duncan.

RUTTER, W. J., KRICHEVSKY, P., SCOTT, H. M. and HANSEN, R. G. **The metabolism of**

lactose and galactose in the chick. *Poultry Sci.*, 1953, **32**, 706-715. [Dept. Dairy Sci., Univ. Illinois, Urbana.]

Day-old chicks received in experiments 1 to 3 a basal diet of the maize and soya bean type; the supplements in experiment 1 were 53.45 per cent. dextrin, lactose, maltose, sucrose or glucose given at the expense of maize. The birds receiving lactose grew least and a significant number developed toe abnormalities; the other groups grew normally. In experiment 2, the diet was given alone, or with 53.45 or 40 per cent. lactose, or 40 per cent. lactose plus 13.45 per cent. ground wheat, ground oats or dried baker's yeast; the average group liveweights were 255, 138, 217, 223, 203 and 167 g., respectively, at 21 days of age. In experiment 3, 10, 20, 40 per cent. lactose and 40 per cent. lactose plus 20 per cent. beet pulp were given at the expense of maize; the 2 lower lactose intakes had no effect on liveweight, although feed efficiency was much lower at the 20 per cent. lactose level. Diarrhoea was troublesome when more than 10 per cent. lactose was given.

The basal diet for experiments 4 to 6 was based on cerelese and casein, the supplements being at the expense of cerelese. In 2 experiments more than 10 per cent. lactose or galactose decreased growth. Curled toe occurred only in groups receiving lactose, but epileptiform convulsions were recorded in chicks receiving more than 10 per cent. galactose for more than 4 or 5 days. Blood reducing sugar was 460 to 470 mg. per 100 ml. at galactose intakes of 15 and 20 per cent. Giving 0.1 per cent. uridine or uracil or 0.01 per cent. vitamin B_{12} , together or separately, did not alleviate the signs and no effect was seen when these substances were injected intravenously.

ASKONAS, B. A. and CAMPBELL, P. N. **Bio-synthesis of milk proteins in the fasting goat.** *Biochim. biophys. Acta.* 1953, **11**, 304-305. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

Methionine labelled with ^{35}S was injected intravenously into a lactating goat on a normal diet and after a 48-hr. fast; samples of milk were taken at short intervals and the activities of the protein fractions were measured.

The activity of casein and whey proteins greatly exceeded that of plasma proteins, suggesting that the mechanism of formation of milk proteins was the same in the normal and the fasting goat and that the blood proteins were not major precursors of the milk proteins. In the normal animal, the maximum activity of the milk proteins occurred $1\frac{3}{4}$ hr., but after fasting, at $4\frac{1}{2}$ hr. after the injection, the difference being due possibly to the considerable reduction of milk output in the fasting condition.—C. Warner.

706

REBER, E. F., WHITEHAIR, C. K. and MACVICAR, R. **The effect of level of protein fed baby pigs.** *J. Nutrition*, 1953, **50**, 451-458. [Oklahoma Agric. Exp. Stat., Stillwater.]

The 5 experimental rations were compounded of casein, lard, lactose and salts so as to have protein contents of 15, 20, 25, 33 and 41 per cent., made up with water into synthetic milks with an energy value of 1190 Cal. per litre, and supplemented with vitamins. In each of 2 experiments 6 littermate baby pigs were used to test 3 of the 5 rations. In the first 12 days a pair were given one of 3 levels of protein, in the following 12 days a pig of each pair was given one of the remaining 2 protein levels and in the next 12 days each pig received the protein level it had not previously been given. The first 3 protein levels were tested in the first experiment, the last 3 in the second experiment. All animals were given isocaloric amounts of the ration at each feed.

With increasing protein content of ration the dry matter required per kg. weight gain decreased, N retention increased, plasma tryptophan increased, and biological value of casein decreased, especially in younger pigs. Plasma protein, Hb and blood nicotinic acid were not significantly affected by protein intake. Efficiency of conversion of dry matter to bodyweight was negatively correlated with age. The ration containing 41 per cent. protein produced maximum weight gain and feed efficiency in very young pigs. As pigs approached 8 weeks of age protein at the 20 per cent. level was used almost as efficiently as at higher levels.—F. C. Aitken.

707

EGGERT, R. G., BRINEGAR, M. J. and ANDERSON, C. R. **Delayed protein supplementation of corn diets for growing swine.** *J. Nutrition*, 1953, **50**, 469-477. [Dept. Animal Husb., Coll. Agric., Univ. Nebraska, Lincoln.]

Groups of 4 weanling pigs were weighed weekly and feed intakes were adjusted to 4.5 or 5.0 per cent. of bodyweight. All were fed twice daily. In one experiment one group was given the protein supplement at both feeds of maize, the other was given all the protein supplement at the morning feed of maize. In the second experiment the interval between maize and protein supplement was lengthened to 36 hr. In the third experiment 4 methods of feeding were compared, maize with supplement, and maize and supplement separated by intervals of 24, 36 and 48 hr. Two replicates of 4 pigs each were used, each replicate forming a separate 4×4 Latin square.

An interval of 24 hr. between supplement and maize did not significantly affect N retention or weight gain. Intervals of 36 and 48 hr. significantly depressed weight gain and reduced N retention by 7 and 14 per cent., respectively. As measured by least significant difference the 14 per cent. reduction was significant, but not the 7 per cent.

The protein supplements used were designed to correct the lysine and tryptophan deficiencies of maize. Protein supplement and maize together gave a diet containing 16 or 17 per cent. protein. F. C. Aitken.

MORIMOTO, H. and HAYASHI, Y. **[Studies on the estimation of nutritive value of protein by components of organs. 1.]** *Bull. Nat. Inst. Agric. Sci., Chiba [G]*, 1953, No. 6, 131-138. In Japanese: English summary.

Rats were fed for a preliminary period on a control diet, fasted for 4 to 7 days and then fed for 8 to 12 days on diets containing fishmeal, wheat bran, soya bean meal, egg powder or cheese. Changes in body weight and weight and N content of liver, kidney, seminal vesicles, testicles and heart were noted. After fasting the N content of

the liver decreased markedly, that of the kidney and seminal vesicles to a less extent; that of the testicles and heart remained the same. The increase in N content of the liver after protein feeding varied according to the kind of protein, but it was difficult to assess nutritive value by this variation. (From summary.)—J. S. Thomson.

HARPER, A. E., MONSON, W. J., BENTON, D. A. and ELVEHJEM, C. A. **The influence of protein and certain amino acids, particularly threonine, on the deposition of fat in the liver of the rat.** *J. Nutrition*, 1953, **50**, 383-393. [Dept. Biochem., Univ. Wisconsin, Madison.]

Rats received a basal diet containing 9 per cent. casein, 0.3 per cent. methionine, 0.13 per cent. choline, sucrose, fats, minerals and vitamins, and nitrogen compounds were tested for effect on growth rate and fat deposition in the liver over periods of from 2 to 5 weeks. An additional 2 per cent. of casein, or a mixture of essential amino-acids, nearly doubled growth rate and nearly halved liver fat content; 6 per cent. of gelatine, or certain mixtures of non-essential amino-acids, had a similar effect on liver fat without affecting growth; 0.1 per cent. of tryptophan increased growth rate without affecting liver fat content and was added to the basal ration in some experiments. The most effective supplement found for reducing liver fat was a mixture of 0.18 per cent. threonine and 1.5 per cent. glycine; threonine alone was better than glycine alone, but neither was as effective as both together. The effect of threonine was slight if choline was omitted from the basal ration.

Glycocyamine with betaine, serine, glycocyamine alone and additional choline and methionine, in that order, had decreasing effects on the liver fat content. Arginine, proline, creatine, ammonium citrate, and combinations of these, had no effect. The accumulation of liver fat caused by the basal diet could be reversed by gelatine. No satisfactory explanation of all these effects is proposed.

C. Warner.

PROTASOVA, T. N. Vliyanie kortina i dezoksi-kortikosterona na vosstanovlenie nekotorykh protsessov azotistogo obmena, narushennykh pri belkovo nedostatochnosti. [The effect of cortin and deoxycorticosterone on the restoration of certain processes of nitrogen metabolism interrupted by protein deficiency.] *Biokhimiya*, 1953, **18**, 89-96. [Lab. Khim. Org., Inst. Biol. Med. Khim., Akad. Med. Nauk SSSR, Moscow.]

When deoxycorticosterone or cortin was subcutaneously injected into white rats with obvious signs of protein deficiency there was a decrease in urine N, an increase in the percentage of urea

relative to total N and a decrease in excretion of amino-acids. The hormones also increased the activity of the enzymes deaminising *dl*-alanine and those oxidising tyrosine and led to increased urea formation in liver slices from protein-deficient animals.

When the test animals were repleted cortin and deoxycorticosterone considerably speeded up complete restoration of these functions. Simultaneous injection of adrenal and thyroid hormones enhanced their effects.—W. Hughes.

CAMPBELL, R. M., SHARP, G., BOYNE, A. W. and CUTHBERTSON, D. P. **Cortisone and the metabolic response to injury.** *Nature*, 1953, **172**, 158-160. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Male rats at about 3 months of age were divided into 4 groups for the following treatments: (1) subcutaneous implantation of 25 mg. cortisone acetate; (2) fracture of femur by open operation; (3) subcutaneous implantation of 50 mg. cortisone acetate; (4) treatments 1 and 2 combined. The increased output of urinary N over the pre-treatment level was similar in groups 1 and 2 and in groups 3 and 4, but the increase in groups 3 and 4 was less than twice that in groups 1 and 2. The magnitude of the responses was apparently conditioned by the amount of hormone implanted and by the presence or absence of injury. The significance of the results is discussed.

HALEVY, S. and GUGGENHEIM, K. **The biological availability of heated wheat gluten-glucose mixtures.** *Arch. Biochem. Biophys.*, 1953, **44**, 211-217. [Lab. Nutrit., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Gluten mixed with water, 0.5 ml. per g., or with water and 1 g. glucose per g. pure protein ($N \times 6.25$), was autoclaved at 120° C. for 2 hr. The effect of heat on the biological value of the protein was measured by estimation of the amino-acids liberated by acid hydrolysis or by digestion with pancreatin for up to 120 hr. The results showed liberation of 83 per cent. less arginine, 50 per cent. less lysine and 7 per cent. less phenylalanine after heating the gluten with glucose than after heating it alone. The other 7 amino-acids were not affected. The results confirm the earlier work of Clandinin *et al.* (Abst. 2260, Vol. 21).

N balance studies with rats, the test proteins forming 9 per cent. of the diet, showed a reduction of digestibility and a very great reduction of biological value of the autoclaved gluten-glucose mixture as compared with the autoclaved gluten. Addition of lysine, alone or with arginine, to the autoclaved mixture restored its biological value to that of gluten autoclaved alone.—W. Godden.

716

SCHROEDER, L. J., IACOBELLIS, M., LEES, H. and SMITH, A. H. **The effect of heat on the nutritive value of milk proteins as influenced by water and fat.** *J. Nutrition*, 1953, 50, 351–360. [Dept. Physiol. Chem., Coll. Med., Wayne Univ., Detroit.]

Dogs received rations containing 10 per cent. protein provided entirely by a dried skimmed milk powder containing 35 per cent. protein. When the dry powder was autoclaved at 15 lb. pressure for 30 min. N balance was negative and digestibility and biological value were reduced, but when the milk powder was reconstituted with water to protein levels of 3.5 or 17.5 per cent. before autoclaving, no change in N balance, digestibility or biological value, as compared with unheated powder, was found.

In tests *in vitro* with whole milk and skimmed milk powders heated in different ways, the amount of amino-N released by crystalline trypsin or chymotrypsin was estimated. Roughly 3 times as much amino-N was liberated by these enzymes from the autoclaved skimmed milk powder if it had been reconstituted at levels of 3.5, 10.5, 17.5 or 24.5 per cent. protein before heating; little water was thus needed to protect the protein against heat injury. The digestibility of the proteins of reconstituted milk *in vitro* was improved by heat treatment. Similar results were obtained with whole milk powder; there may have been slight additional protection of the protein by the fat present.—C. Warner.

FINK, H., SCHLIE, I. and RUGE, U. **Über die Zusammensetzung, die Verdaulichkeit und die**

Eiweiss-Qualität des Mycels von *Penicillium notatum*. Ein Beitrag zur Verwertung der Pilzabfälle bei der Penicillin-Gewinnung. [Composition, digestibility and protein quality of the mycelium of *Penicillium notatum*; a contribution to the utilisation of mould residues from the production of penicillin.] *Hoppe-Seyler's Ztschr.*, 1953, 292, 251–263. [Ernährungsphysiol. Abt., Inst. Gärungswiss., Univ. Cologne.]

Seven samples of mycelium of *Penicillium notatum*, residues from penicillin factories, gave on analysis a crude protein content of 27 to 31 per cent. of the dry matter and an ash content of 28 to 34 per cent. A complete ash analysis of one sample showed P_2O_5 32.5 and CaO 21.18 per cent. Studies of 2 samples of mycelium *in vitro*, with solutions of pepsin, trypsin and diastase, gave 44 and 48 per cent. digestibility for dry matter and 77 and 69 per cent. for crude protein. Estimations on adult rats *in vivo* gave 50 and 51 per cent. digestibility for dry matter, and 59 and 58 per cent. for crude protein.

The biological quality of the protein was tested on young rats in experiments lasting 90 to 120 days, preliminary tests having shown that the mycelium would be eaten by rats without injurious effect. The diet contained 32.4 per cent. dried mycelium, which supplied 77 per cent. of the protein intake. The biological value of the protein, average 59.8 per cent., was inferior to that of milk protein, but similar to that of other plant proteins. It was approximately equal to that of *Torula utilis* or of potato. There was no evidence of an "animal-protein-factor" effect, or an aureomycin effect. The experiments indicate the possibility of using the mycelium residues as a source of protein in animal feeding.—M. B. Richards.

SURE, B. (with EASTERLING, L., DOWELL, J. and CRUDUP, M.) **Improving the nutritive value of cereal grains. 1. Improvement in the efficiency of the proteins in milled wheat flour with lysine, valine, threonine and an extract from condensed fish solubles.** *J. Nutrition*, 1953, 50, 235–244. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Groups of 6 male and 6 female rats were given to appetite for 6 weeks a basal diet of white flour 86.4, cellu flour 2.0, salts 4.0, vegetable shortening 3.0, cod liver oil 2.0, wheat germ oil 1.0, cerelese 1.6 per cent. and vitamins of the B complex. The protein content was about 9 per cent. A supplement of 0.4 per cent. L-lysine increased growth, protein efficiency and weight gain per g. N intake, which were further increased by addition of 0.2 per cent. DL-threonine, although threonine without lysine had a depressing effect. Addition of 0.7

N.A. and R., January 1954

per cent. DL-valine to lysine and threonine and, better still, addition of an extract of condensed fish solubles to the 3 amino-acids further increased growth, protein efficiency and weight gain per g. N intake. The last was equal to the weight gain per g. N obtained with a ration containing 10 per cent. protein derived from dried non-fat milk solids.

In an experiment lasting 12 weeks a supplement of vitamin B₁₂ added to the basal diet plus lysine gave an appreciable increase in growth due to increased food consumption in male but not female rats.

Rats on the basal ration supplemented with the 3 amino-acids with or without the fish solubles extract were bred. During pregnancy and lactation extra fat-soluble vitamins were given, and during lactation extra threonine and tryptophan. Reproduction was satisfactory but lactation was not optimum.

Economy of food utilisation was studied with 4 groups of 6 weanling rats given basal ration, basal with lysine, with lysine and valine and with all 3 amino-acids. During the first 6 weeks, when food intake was restricted to 7 g. daily, lysine alone and with valine gave equal increases in food economy. The addition of threonine gave a further increase. During the next 6 weeks, when food was allowed to appetite, each successive supplement stepped up the economy of food utilisation.—F. C. Aitken.

719

SURE, B. (with EASTERLING, L., DOWELL, J., CRUDUP, M. and SCRIMSHAW, N. S.) **Protein efficiency. Improvement in whole yellow corn with lysine, tryptophan, and threonine.** *J. Agric. Food Chem.*, 1953, **1**, 626–629. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

In tests in which groups of 12 young rats were fed to appetite for 6 weeks addition of lysine increased growth and protein efficiency of U.S. yellow maize, and tryptophan caused a further increase, but with methionine or threonine there was no additional increase. Addition of threonine to the supplement of 3 amino-acids caused a marked increase in growth and feed consumption but not in protein efficiency.

In N retention tests in which the diet was given to appetite the biological value of the U.S. yellow maize supplemented with lysine, tryptophan and methionine was increased 7 per cent. by addition of 0.5 per cent. DL-threonine.

In subsequent experiments with U.S. yellow maize and 2 types of Guatemala yellow maize, food was restricted to 7 g. daily for 15 days and for the next 30 days was given to appetite. With the U.S. maize 0.5 per cent. DL-threonine increased

protein efficiency when added to a supplement of 0.4 per cent. L-lysine, 0.5 per cent. DL-tryptophan and 0.5 per cent. DL-methionine, but not when methionine was omitted. The percentage increases were 33.3 during restricted feeding and 21.7 during the next 30 days. With the Guatemala maize DL-threonine increased protein efficiency when added to L-lysine and L-tryptophan in the absence of methionine.

The 3 samples of maize had the same methionine content. Protein contents were 8.94 (U.S.), 8.3 and 9.1 (Guatemala) per cent. The basal U.S. maize diet consisted of maize 86, salts 4, vegetable fat 3, cod liver oil 2, wheat germ oil 1 and cerelese 4, with B vitamins. In the Guatemala maize diets maize formed 86.9 or 79.3 per cent. with corresponding differences in cerelese content. The diets contained 7.7 or 7.2 per cent. protein.

CARROLL, R. W., HENSLEY, G. W., SITTLER, C. L., WILCOX, E. L. and GRAHAM, W. R. (Jr.) **Absorption of nitrogen and amino acids from soybean meal as affected by heat treatment or supplementation with aureomycin and methionine.** *Arch. Biochem. Biophys.*, 1953, **45**, 260–269. [Res. Labs., Quaker Oats Co., Chicago, Ill.]

Rats received rations in which raw or heated solvent soya bean meal was the sole protein source and which contained chromic oxide as marker. The total N content of the diet was 3.5 per cent. After 3 days the animals were killed and samples of faeces and of the contents of the terminal part of the small intestine, caecum and colon were taken for analysis. As calculated from the nitrogen : chromic oxide ratios, absorption of N was greater from the heated than from the raw meal, particularly in the small intestine. A larger proportion of the N of raw meal was absorbed from the caecum or colon.

Aureomycin supplementation increased N absorption from the small intestine, and with heated meal, but not with raw, there was a slight increase in the total N absorbed. Methionine supplementation had no effect on the amount or site of N absorption. The absorption of lysine, leucine and methionine resembled that of total N; however, with cystine there was a large relative excess in the small intestine of animals given the raw meal. The unabsorbed cystine appeared to be destroyed, presumably by micro-organisms, lower down in the intestinal tract; this process was inhibited by aureomycin. The failure to absorb cystine in the small intestine and its later destruction might explain previous findings on the effect of adding cystine or methionine to diets containing raw soya bean meal.—C. Warner.

721

HENSLEY, G. W., CARROLL, R. W., WILCOX, E. L. and GRAHAM, W. R. (Jr.) **The effects of aureomycin and methionine supplements fed to rats receiving soybean meals.** *Arch. Biochem. Biophys.*, 1953, **45**, 270-274. [Res. Labs., Quaker Oats Co., Chicago, Ill.]

Rats received diets containing a small amount (1.6 per cent. total N) of raw or heated solvent soya bean meal as sole protein source and supplemented with 0.02 per cent. aureomycin or 0.5 per cent. methionine or both. Gain in weight and efficiency of feed utilisation were measured for 49 days. Aureomycin increased growth and utilisation of both raw and heated meals, but the degree of improvement with raw meals was very much greater. Methionine alone produced a similar but slightly greater effect; methionine with aureomycin had little additional effect in female rats but increased the weight gain of males.

It is suggested that, in the absence of antibiotic, potentially available dietary methionine may be lost to the animal as a result of the activities of the intestinal microflora; this effect is greater with raw than with heated meal, because with the former there is a tendency for N to pass further down the intestinal tract, and hence into regions of greater microbial activity, before absorption.

C. Warner.

ELMAN, R. **Time factors in the utilization of a mixture of amino acids (protein hydrolysate) and dextrose given intravenously.** *J. Clin. Nutr.*, 1953, **1**, 287-294. [Dept. Surg., Sch. Med., Washington Univ., St. Louis, Mo.] Spanish summary.

N balance studies on 4 subjects given glucose and amino-acids together or separately showed that utilisation of an infused amino-acid mixture was increased by simultaneous infusion of glucose and was better when infusion with glucose was slow than when it was fast. Glucose utilisation was increased by simultaneous infusion of amino-acids.—F. C. Aitken.

726

MUNRO, H. N. and THOMSON, W. S. T. **Influence of glucose on amino acid metabolism.** *Metabolism*, 1953, **2**, 354-361. [Dept. Biochem., Univ. Glasgow.]

Administration of 50 mg. glucose to 6 fasting men reduced plasma amino-N by 12 per cent. in 1 hr. At the end of 2 hr. the level had risen slightly, but by the 3rd hour it had not reached fasting level. Administration of 30 g. fat in place of glucose caused a gradual decline amounting to a fall of 4.4 per cent. at 3 hr. The effect of glucose was highly significant, the effect of fat of borderline significance. A similar effect of glucose was found in rats. Microbiological estimates of plasma essential amino-acids after glucose administration to the 6 subjects showed that the relative reductions in levels of essential amino-acids, the value for tryptophan being taken as 1.0, follow the pattern of man's relative requirements of these amino-acids, tryptophan again being taken as 1.0.

Microbiological estimation of free and total tryptophan excretion in the urine of 4 men after glucose ingestion failed to substantiate the claim of Albanese *et al.* (Abst. 4714, Vol. 17) that glucose ingestion causes an immediate fall in tryptophan excretion.—F. C. Aitken.

WHARTON, M. A. and PATTON, M. B. **Amino acid excretion on different protein intakes.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 762-764. [Ohio Agric. Exp. Stat., Columbus.]

Of 18 women in 2 groups, some received on the average 148 mg. N and the others 196 mg. N per kg. bodyweight daily from foods described as "common to the American dietary". The first

N.A. and R., January 1954

group had an average N balance of about + 5, the second of + 32 mg. per kg. The second group received 5 to 13 per cent. more of arginine, histidine, isoleucine, leucine, lysine, phenylalanine, threonine and valine than the first, but no significant difference could be found in the urinary excretion of these amino-acids. There was, however, great individual variation in the amounts of these amino-acids excreted, particularly histidine, which was excreted in the largest quantity.—C. Warner.

ABBASY, A. S. and EISA, E. A. **The excretion of methionine in children in health and disease with a note on the value of methionine tolerance test as an index of liver function.** *Arch. Pediat.*, 1953, **70**, 146-156. [Dept. Paediat., Fac. Med., Univ. Alexandria.]

The daily urinary output of methionine, estimated in 67 healthy children, was not greatly influenced by variations in fluid intake. It amounted on the average to 33 mg. between the ages of 2 and 5 years, 61.5 mg. at 5 to 10 years, and 131 mg. at 10 to 15 years. In 30 healthy adults it ranged from 160 to 400 mg. The tolerance test consisted in intravenous injection of 50 mg. methionine per kg. bodyweight and collection of urine for 9 hr. afterwards. In 6 healthy children not more than 2.8 per cent. of the test dose was excreted during this time, but in 3 with hepatitis and severe jaundice the proportion was 9.2 to 21.8 per cent. The 24-hr. output of methionine in disease was studied in 39 children; it was consistently above the levels of excretion in health only in those with acute pneumonia or hepatitis.

CAREDDU, P. Osservazioni sulla aminoacidemia e sulla aminoaciduria dopo il carico con idrolizzato proteico in bambini distrofici. [Amino-acid content of the blood and urine in dystrophic children after administration of protein hydrolysates.] *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1938-1939. [Clin. Pediat., Univ. Sassari.]

Amino-N was estimated in the blood and individual amino-acids were identified by paper chromatography in the serum and urine of normal and dystrophic children, with and without administration of protein hydrolysates. In normal children blood amino-N rose to a peak 2 hr. after administration of hydrolysates and returned to normal

within 4 hr. In the dystrophic children the increase was slower and the maximum, which was lower, was reached after 4 hr.

The amino-acids identified in the serum of normal and dystrophic children were aspartic acid, glutamic acid, serine, taurine, glycine, alanine, proline, valine, leucine and phenylalanine. They did not change after administration of protein hydrolysates, but the spots on the chromatogram were darker.

In the chromatogram of the urine, after administration of hydrolysates, no change occurred with the normal children, but in samples from dystrophic children new spots appeared. The amino-acids identified before administration were glycine, alanine and β -alanine; afterwards aspartic acid, glutamic acid, serine, tyrosine, proline, phenylalanine, leucine and several unidentified substances appeared.—E. M. Hume.

731

GINGRAS, R. Contribution à l'étude du métabolisme de quelques acides aminés. [Metabolism of some amino-acids.] *Laval méd.*, 1953, **18**, 727-744. [Fac. Méd., Laval Univ., Québec.]

This lecture gives some account of work by the author and his colleagues on the use of synthetic amino-acids in the nutrition of the rat. Hexoserine given as 1 per cent. of the diet produced retardation of growth and disturbances of protein metabolism as shown by a low serum protein value and raised values for muscle creatine and urinary creatinine. Anaemia also occurred, and the effects of hexoserine appeared to be those of an antagonist to lysine. Pentoserine was synthesised and given to rats and chicks. It had no apparent effect on the growth of the rat but seemed to act as a precursor of arginine for the chick. Analogues of methionine and cystine had no obvious effect on growth or fat deposition in rats. Further studies of unnatural synthetic amino-acids are to be made.—A. M. Copping.

FROST, D. V. and SANDY, H. R. **Effects of mineral deficiencies on amino acid utilization. Critical role of potassium and phosphorus.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 102-105. [Abbott Labs., N. Chicago, Ill.]

Rats were depleted on a protein-free diet and were then given daily 18.5 ml. of a 5 per cent. fibrin hydrolysate, containing 0.24 g. N, with mineral mixtures. Lack of Ca, Mg or Na in the diet had little effect on the growth response. A diet lacking P supported slow growth, but lack of K resulted in considerable loss of weight, with haemorrhage leading to death if untreated; a prompt growth response was observed when either deficiency

was corrected. The K requirement in these conditions was found to be about 14 mg. daily. The addition of 10 m. equiv. KH_2PO_4 per litre to 5 per cent. protein hydrolysates for intravenous use is recommended.—C. Warner.

ARNSTEIN, H. R. V. and NEUBERGER, A. **The synthesis of glycine and serine by the rat.** *Biochem. J.*, 1953, **55**, 271–280. [Nat. Inst. Med. Res., Mill Hill, London.]

For the composition of the amino-acid diets see Arnstein and Neuberger (Abst. 487, Vol. 24). Groups of rats at weaning received one of these diets or a basal casein diet containing $\alpha\text{-}^{14}\text{C}$ -glycine 20, unextracted casein 125, salt mixture 40, cod liver oil 16, arachis oil 64, cane sugar 340 and maize starch 395 parts. After 20 to 39 days animals were killed for isolation of serine and glycine from the viscera or whole carcass. Several groups received supplements of vitamin B_{12} , choline or methionine, separately or together.

The specific activity of glycine from the visceral proteins was about 40 per cent. of that of the dietary glycine, and it was not affected by growth rate. Glycine from the mixed carcass proteins

always had a lower specific activity, 45 to 92 per cent. of that of visceral glycine, but its activity increased with increasing growth rate.

Glycine formation was constant at about 133 mg. per rat daily, independent of glycine intake, and serine formation at about 350 mg., suggesting that most of the body glycine was derived from serine. The activity of body glycine was always 20 to 35 per cent. greater than that of the serine.

The appearance of labelled C from the $\alpha\text{-C}$ atom of dietary glycine in the $\beta\text{-C}$ atom of serine was proportional to the glycine intake, suggesting that endogenous glycine is not an important source of the $\beta\text{-carbon}$ of serine and that the conversion is used mainly to deal with excess dietary glycine. It is considered that the relatively constant glycine level of the tissues is maintained by regulation of its degradation, not of its formation.—D. Duncan.

ROTHSTEIN, M. and MILLER, L. L. **The conversion of L-lysine-6- C^{14} to pipecolic acid in the rat.** *J. Amer. Chem. Soc.*, 1953, **75**, 4371–4372. [Dept. Radiation Biol., Sch. Med. Dent., Rochester, N.Y.]

After L-lysine-6- C^{14} monohydrochloride had been injected intraperitoneally into rats, urine collected for 24 hr. was found to contain a radio-active constituent corresponding to L-pipecolic acid. The high specific activity is taken to indicate that the acid is involved in the conversion of L-lysine to α -aminoadipic acid.—D. Harvey.

738

HEATH, H., RIMINGTON, C., GLOVER, T., MANN, T. and LEONE, E. **Studies using radioactive sulphur on ergothioneine formation in the pig.** *Biochem. J.*, 1953, **54**, 606–611. [Dept. Chem. Pathol., University Coll. Hosp. Med. Sch., London, W.C.1.]

Ergothioneine, secreted by the seminal vesicles, is a normal constituent of boar semen. In the present experiments 2 boars were given ^{35}S -labelled sulphate, thiolhistidine, methionine or ergothioneine and the distribution of ^{35}S was studied in the blood, urine and semen. Neither sulphate nor thiolhistidine was utilised in the formation of ergothioneine. The S of methionine was incorporated into ergothioneine and dietary ergothioneine appeared in the seminal plasma.

W. Godden.

739

ARNSTEIN, H. R. V. and CRAWHALL, J. C. **The metabolism of DL- $[\beta\text{-}^{14}\text{C}]$ and DL- $[\text{C}^{35}\text{S}]$ cystine by the rat.** *Biochem. J.*, 1953, **55**, 280–285. [Nat. Inst. Med. Res., Mill Hill, London.]

When fed on $\beta\text{-}^{14}\text{C}$ -cystine with α -amino- γ -phenylbutyric acid and *p*-aminobenzoic acid, rats excreted in the urine methyl-labelled acetate as

N.A. and R., January 1954

acetaminophenylbutyric acid; similar results were obtained with γ - ^{14}C -valine or α - ^{14}C -acetate. Very little radio-activity was found in urinary hippuric acid. On degradation of visceral proteins, high activity was found in glutamic acid, aspartic acid and alanine as well as cystine, low activity in serine and glycine and lower in methionine, leucine, valine and threonine. Choline from carcass and viscera was slightly labelled. When ^{35}S -cystine was given, the methionine of the visceral protein had only 0.7 per cent. of the activity of cystine from the same source.

It was concluded that the major pathway of cysteine metabolism is to pyruvate, that the β -carbon atom of cystine is not a precursor of methyl groups, and that, in confirmation of nutrition experiments, the synthesis of cystine from methionine and serine through cystathionine is not reversible to any appreciable extent.—C. Warner.

DE BASTIANI, G., GRANATA, L. and SPERTI, L. Azione diabetogena di estratti di ipofisi anteriore nel ratto albino a dieta povera in cistina. [Diabetogenic action of anterior pituitary extracts for the albino rat given a diet poor in cystine.] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 224-227; 227-229. [Ist. Fisiol., Univ. Padua.]

Of 30 rats of weight about 100 g. maintained for 100 days on a diet low in cystine (Abst. 471, Vol. 4), 10 received no treatment, and the remainder were given twice a day an intraperitoneal injection of glucose increasing from 0.5 to 3.0 g. daily. Every 8 or 10 days one or two rats were killed. The rats given glucose showed in the first 15 to 20 days a moderate reduction of blood sugar, but after about 30 days 75 per cent. of them showed a steady rise accompanied by loss of weight, hunger and polyuria. Histological examination of the pancreas showed diabetic changes.

Two groups of 20 rats of weight about 100 g. were fed for 80 days on the same diet low in cystine, and one group received in addition for the last 40 days a daily intraperitoneal injection of anterior pituitary hormone increasing from 3 to 10 units. Another 20 rats received the same injections and a stock diet. In the group having stock diet growth was accelerated and there was slight reduction of blood sugar. There was some hyperplasia and hypertrophy of the islet tissue of the pancreas. In the rats having the diet poor in cystine, treatment with anterior pituitary hormone caused early loss of weight. Blood sugar fell at

first but after about the 30th day was above normal, and there were signs of degeneration in the islet tissue.—E. M. Hume.

AWAPARA, J. and WINGO, W. J. On the mechanism of taurine formation from cysteine in the rat. *J. Biol. Chem.*, 1953, **203**, 183-188; 189-194. [M. D. Anderson Hosp. Cancer Res., Univ. Texas, Houston.]

In continuation of earlier work (Abst. 651, Vol. 20) it is shown that a third compound in addition to alanine and taurine is formed in the liver of the rat after intravenous injection of cysteine. This compound was isolated and shown to be 2-aminoethanesulphinic acid. It was identical with a synthetic sample prepared from taurine by benzylation and subsequent reduction and hydrolysis of the sulphonyl chloride. It is probably identical with the hypotaurine reported by Chatagner and Bergeret (*C.R. Acad. Sci.*, 1951, **232**, 448). On oxidation with 30 per cent. H_2O_2 it was converted quantitatively to taurine.

After intravenous injection of cysteine labelled with ^{35}S , chromatographic examination of liver extracts showed the presence of significant amounts of both 2-aminoethanesulphinic acid and taurine labelled with ^{35}S . Cysteic acid was not detected.

WILLIAMSON, M. B. and FROMM, H. J. Utilization of sulfur amino acids during healing of experimental wounds. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 329-333. [Dept. Biochem., Sch. Med., Loyola Univ., Chicago, Ill.]

Rats received a protein-free diet for 5 days before being wounded by removal of skin from the back of the neck. The basal diet was then supplemented for half the 36 rats with 60 mg. DL-alanine per 100 g. diet, and for the remainder with 100 mg. DL-methionine per 100 g. diet. Two days after wounding each rat received a subcutaneous injection of 0.85 mg. methionine labelled with ^{35}S , and groups were killed 3, 6 and 10 days later.

The ^{35}S content of regenerating wound tissue increased with time, but that of normal skin, liver

and muscle decreased. Total S showed the same trend, but in a much smaller degree. There was a low N concentration in healing wound tissue; it rose with the progress of healing.

Partition of ^{35}S into cystine- and methionine- ^{35}S showed that in wound tissue the greater part of the ^{35}S was in cystine, and the rate of deposition of cystine in the healing tissue was greater than that of methionine. The rate of healing was found to be directly proportional to the rate of cystine deposition.—D. Duncan.

LANG, K. and MAYER, U. **Über Bildung und Abbau von L-Oxyprolin. [Formation and destruction of L-hydroxyproline.]** *Biochem. Ztschr.*, 1953, **324**, 237–240. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

By means of the proline oxidase present in mitochondria, L-hydroxyproline was oxidised to the half-aldehyde of γ -hydroxyglutamic acid, which other workers had conjectured to be an intermediate product in the breakdown of hydroxyproline. The substance was isolated in the form of its dinitrophenylosazone and its constitution was studied. Attempts to demonstrate oxidation of L-proline to hydroxyproline failed because of the high content of proline oxidase in the organs used, which destroyed the proline and hydroxyproline so rapidly that no increase of hydroxyproline could be demonstrated.—M. B. Richards.

Additions of 5 to 50 mg. DL-valine daily to diets containing protein of inferior quality, e.g., potato protein, wheat gluten or rice gluten, proved toxic to young rats. After 14 days many showed haemorrhages and necroses on the tail and hind legs and the fur became rough and lustreless. Many animals died within 4 weeks. Comparative

experiments with L- and D-valine showed clearly that the toxicity of DL-valine was due to the D-component. With diets containing high-quality protein, e.g., wheat groats and whole powdered milk, additions of DL-valine were not toxic, except for slight transient changes in skin and fur.

LEVINE, M. and FOPEANO, J. V. (Jr.) **Effect of ethionine on protein content of liver in growing rats.** *J. Biol. Chem.*, 1953, **202**, 597–605. [Dept. Biol. Chem., Med. Sch., Univ. Michigan, Ann Arbor.]

Rats were given diets of casein, sucrose, starch, fats, salts and vitamins, with or without choline, and the effect of adding ethionine to the diet was studied. Controls without ethionine were paired with experimental animals or fed to appetite. The inhibition of growth in rats of both sexes given ethionine appeared to be partly due to their lower food intake, particularly in the animals not receiving choline. The rats given ethionine showed smaller weight gains per g. food consumed than the paired controls. The livers of rats of both sexes receiving ethionine but not choline contained more water than those of controls; when choline was given there was no difference. Male rats receiving ethionine but not choline tended to have a lower liver lipid content than controls fed to appetite, but not lower than pair-fed controls. Ethionine given to male rats receiving choline, or to female rats with or without choline, resulted in a higher liver lipid content than in control groups.

Rats of both sexes receiving ethionine but not choline had a higher liver protein content, expressed as percentage of bodyweight, than pair-fed animals, though not higher than those fed to appetite. Addition of choline to the diet reduced these differences below the significant level. It is suggested that ethionine in the diet brings about formation of abnormal protein which accumulates in the liver; addition of choline spares methionine to antagonise the effects of ethionine.—C. Warner.

BENEDICT, J. D., YÜ, T. F., BIEN, E. J., GUTMAN, A. B. and STETTEN, D. (Jr.) **A further study of the utilization of dietary glycine nitrogen for uric acid synthesis in gout.**

BIEN, E. J., YÜ, T. F., BENEDICT, J. D., GUTMAN, A. B. and STETTEN, D. (Jr.) **The relation of dietary nitrogen consumption to the rate of uric acid synthesis in normal and gouty man.** *J. Clin. Invest.*, 1953, **32**, 775-777; 778-780. [Div. Nutrit., Pub. Health Res. Inst. City of New York, Inc.]

Two normal and 4 gouty subjects, 2 of whom were excreting excessive quantities of uric acid in the urine, were maintained on a low-purine, restricted-protein diet. After 5 to 10 days each received ^{15}N -labelled glycine by mouth, and urine was then collected for 9 days.

The 2 subjects with high uric acid excretion excreted isotope in far higher concentration than the normal controls, with maxima on the 2nd instead of the 4th day. In the other 2 gouty subjects the effect was slight or absent. The first 2 eliminated a larger fraction of the ingested glycine N as uric acid. It is not known whether there are 2 distinct types of gouty metabolism or whether the results indicate different stages of the same process.

Uric acid production after administration of ^{15}N -labelled glycine was studied in a normal subject and one with gout who excreted excessive quantities of uric acid. Each subject was studied while on a low-purine diet and on the same diet with added skimmed milk powder to increase the protein intake.

In both subjects the incorporation of ^{15}N into uric acid was more rapid on the high-protein diet, and a greater fraction of the labelled glycine N was excreted in the total urine N.

The results appear to support the advisability of restricting dietary protein where reduction of uric acid formation is desirable.—D. Duncan.

DINTZIS, R. Z. and HASTINGS, A. B. **The effect of antibiotics on urea breakdown in mice.** *Proc. Nat. Acad. Sci., Washington*, 1953, **39**, 571-578. [Dept. Biol. Chem., Med. Sch., Harvard Univ.]

Tissue from the stomach, small intestine, caecum and colon of mice was incubated with ^{14}C -labelled urea and $^{14}\text{CO}_2$ was collected as an indication of urease activity. The urea breakdown was found to be related to the presence of bacteria in the suspending medium. When mice were fed on a diet containing sulphaguanidine, terramycin and penicillin in order to reduce the intestinal bacterial count to a low level, there was no urease activity in similarly prepared tissues.

Breakdown of labelled urea given intraperitoneally *in vivo* was almost completely eliminated in mice given the antibiotic mixture or penicillin alone. It is therefore considered that urease activity in mammals, a potential source of ammonia poisoning, is due to the presence of bacteria.

GRAY, F. V., PILGRIM, A. F. and WELLER, R. A. **Conversion of plant nitrogen to microbial nitrogen in the rumen of the sheep.** *Nature*, 1953, **172**, 347-348. [Div. Biochem. Gen. Nutrit., C.S.I.R.O., Univ. Adelaide.]

In sheep fed on wheaten hay there was more than twice as much N per g. lignin in fodder as in the plant residues in the rumen, and more than

half the total rumen N was in the micro-organisms. Sheep slaughtered at intervals of 2½ to 16 hr. after feeding showed that these proportions did not vary greatly, as microbial N varied from 45 to 54 per cent. of the total. There is, therefore, considerable conversion of plant to microbial N and no significant gain or loss of N in the rumen except

by passage of the contents to lower levels of the digestive tract; the losses due to absorption of ammonia are small on a diet of wheaten hay.

JIMÉNEZ DÍAZ, C., ROMEO, J. M. and MARINA, C. Ulteriores estudios sobre la significación y genesis de las esteatorreas. [Further studies on the nature and etiology of steatorrhoea.] *Rev. clín. española*, 1953, **49**, 367-374. [Inst. Invest. Méd., Fac. Med., Madrid.] English, German and French summaries.

Direct estimations of fat in fresh faeces, confirmed by calculation from data obtained by bomb calorimetry on the dried faeces, showed that in some patients with idiopathic steatorrhoea the elimination of fat was greater than the intake. This was particularly evident on a low-fat diet. Moreover, fat elimination was sometimes higher on basal days with a 30 g. intake than on days with an intake of 130 g. The data support the view that idiopathic steatorrhoea is due, not to faulty absorption of fat, but to an increase in fatty secretion from the intestines. Ligature of the thoracic duct in dogs gave rise to steatorrhoea as long as the stasis of chyle persisted. The increase of fat elimination occurred in the contents of an isolated loop as well as in the faeces. It is possible that the

fat secretion which causes steatorrhoea is chyle discharged into the intestinal lumen instead of passing into circulation.—M. B. Richards.

763

COOKE, W. T., THOMAS, G., MANGALL, D. and CROSS, H. **Observations on the faecal excretion of total solids, nitrogen, sodium, potassium, water and fat in the steatorrhoea syndrome.** *Clin. Sci.*, 1953, **12**, 223-234. [Dept. Med., Univ. Birmingham.]

The results of analyses of faeces from patients with the steatorrhoea syndrome showed significant correlations between water, Na, K, fat, N and total solids. Though such correlation might have no functional significance, it was concluded that the correlations between fat content and total solids and between fat and total N might be of empirical significance. Partial correlation coefficients showed a significant direct correlation between water and Na excretion, but not between water and fat or between fat and Na excretion.

For analysis of the K figures it was necessary to consider the results in patients with formed stools separately from those in patients with diarrhoea. The mean K excretion in controls was 9.87 m. equiv. daily, in 4 patients with steatorrhoea and formed stools 22.75 m. equiv. daily; there was no significant difference between the 2 groups, but the variability was significantly greater in the steatorrhoea group. The administration of K by mouth made no significant difference in the faecal output, which suggested that the increase in K excretion in steatorrhoea was not related to impaired absorption. In 2 patients with diarrhoea the impaired K excretion seemed to be associated with increased water excretion.

No correlation was shown between fat excretion and diarrhoea, and in 2 patients with severe diarrhoea the amount of fat excreted greatly exceeded the total fat intake. Even when patients were given low-fat diets the daily fat excretion might greatly exceed the daily fat intake. When a large amount of butter was added to the diet of a severely ill patient nearly all the extra fat was absorbed. All these observations suggest that in patients with the steatorrhoea syndrome endogenous fat excretion is increased. It is suggested

that abnormalities of fat metabolism should be assessed on the amount of fat excreted and not on percentage absorption.—L. Wills.

HERZSTEIN, J., WANG, C. and ADLERSBERG, D.
Fat-loading studies in relation to age. *Arch. Int. Med.*, 1953, **92**, 265–272. [Dept. Med., Mount Sinai Hosp., New York.]

Attempts at chylomicron counting in serum or plasma were unsuccessful. The test was therefore limited to the study of total lipids and lipid fractions in the serum of young and elderly subjects after a fat meal. The subjects were in hospital, 10 aged 17 to 34, mean 24.9 years, and 11 aged 15 to 71, mean 62.0 years. Before the fat meal fasting total serum lipids in the 2 groups were not significantly different. Two hours after the test meal the mean rise for both groups was the same. The concentration in the young group fell almost to fasting level by the sixth hour. That of the older group was still high at 4 and 6 hr. and had not reached fasting level 24 hr. after the meal. A group of 6 blood donors aged 46 to 58, mean 50.3 years, responded like the young group.

FULLERTON, H. W., DAVIE, W. J. A. and ANASTASOPOULOS, G. **Relationship of alimentary lipaemia to blood coagulability.** *Brit. Med. J.*, 1953, **ii**, 250–253. [Dept. Med., Univ. Aberdeen.]

In 8 patients whose meals contained from 12 to 30 g. fat there was no significant variation in the prothrombin time as estimated with Russell viper venom during the day. In 5 subjects given a breakfast containing 65 g. fat there was an average reduction of 4.9 sec. in the clotting time at the height of postprandial lipaemia; when the fat content of the meal was raised to 85 g. the average reduction was 9.8 sec. When thromboplastins which contained large amounts of lipid were used, no reduction in clotting time was shown. Similar experiments in which the clotting time was estimated in silicone-treated tubes without thromboplastin showed that there was significant alteration in the clotting time only in subjects who showed macroscopic fat in blood up to 4 hr. after meals. It is suggested that the increased coagulability produced by fat may play a part in the increased incidence of thrombosis in conditions in which blood fat is high. The relation of thrombosis to a high fat intake and to arteriosclerosis is also discussed.—L. Wills.

TULLOCH, J. A., OVERMAN, R. S. and WRIGHT, I. S.
Failure of ingestion of cream to affect blood coagulation. *Amer. J. Med.*, 1953, **14**, 674–

Vol. 24, No 1.

680. [Dept. Med., Cornell Univ. Med. Coll., New York.]

In a repetition of the work of Waldron *et al.* (*Gastroenterol.*, 1951, **17**, 360) the authors were unable to confirm the findings of these workers on the effect of ingested fat on the blood coagulation time. This they attribute to the fact that they used fresh cleaned and sterilised glass syringes for each venepuncture; the former workers used one syringe throughout each experiment, the syringe simply being washed in water and saline between punctures. They demonstrate that thrombin activity is present on the surface of glass syringes used in this way. Their findings raise doubts whether the fat of milk affects the clotting mechanism of blood.

POMERANZE, J., BOYD, L. J. and GOLDBLOOM, A. A.
Clinical studies in geriatrics. 1. Serum lipid partitions. *Arch. Int. Med.*, 1953, **91**, 740–743. [Bird S. Coler Hosp. Med. Coll., New York.]

Total lipids, total cholesterol, cholesterol esters and phospholipins were estimated in blood serum from 26 male patients aged from 80 to 101 years and showing no clinical evidence of malnutrition. X-ray examinations indicated marked calcification of all larger and medium-sized arteries. All values for cholesterol were below 200 mg. and 5 were below 150 mg. per 100 ml. serum; the mean value was 188 ± 80 mg. per 100 ml. Serum lipid values were unrelated to weight, blood pressure or the occurrence of cardiovascular abnormalities, and in most subjects the phospholipin: cholesterol ratio was one not considered to be associated with atherosclerosis.—D. Harvey.

768

JACOBSON, N. L., ZALETEL, J. H. and ALLEN, R. S.
Effect of various dietary lipids on the blood plasma lipids of dairy calves. *J. Dairy Sci.*, 1953, **36**, 832–842. [Dept. Dairy Husb., Iowa Agric. Exp. Stat., Ames.]

Fifteen calves were suckled by their dams for 3 days after birth and were then divided into 5 comparable groups and fed on whole milk from the 4th to the 18th day. For the next 28 days one group continued to receive whole milk while the other groups were given synthetic milks consisting of 3 per cent. butterfat, crude or hydrogenated soya bean oil or lard and 10 per cent. fat-free dry milk solids; the diets were given twice daily at the rate of 10 lb. daily per 100 lb. bodyweight. Venous blood samples were taken 3 hr. after the morning feed when the animals were 11 days old and thereafter weekly. Ethanol-ether extracts of plasma were analysed for neutral fat, phospholipins, free and esterified cholesterol and free esterified fatty acids; plasma fat was estimated by the standard Allen method.

Total plasma lipids rose sharply in each group during the preliminary whole milk feeding period; except for the group which continued to receive whole milk, there was a sharp fall in plasma total lipid values as soon as the experimental diet was given. After this the group given crude soya bean oil showed a big increase in plasma lipids, which approached the value for animals fed on whole milk, and smaller increases in plasma lipids occurred in the calves given butterfat or lard. The decline in plasma lipids in the group given hydrogenated soya bean oil continued to the end of the experiment. Trends in components of the lipid fractions corresponded to those for total lipids, except that changes in the amounts of neutral fat and free fatty acids were not so large as those in the other fractions.—G. A. Garton.

770

WADDELL, W. R., GEYER, R. P., SASLAW, I. M. and STARR, F. J. **Normal disappearance curve of emulsified fat from the blood stream and some factors which influence it.** *Amer. J. Physiol.*, 1953, **174**, 39-42. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Male albino rats were given intravenous injections of 2.5 mg. fat per g. bodyweight, in emulsions prepared from coconut, olive, cottonseed, linseed or mineral oil or cocoa butter with 3 per cent. cerebroside or 1 per cent. Demal-14 as the emulsifying agent. The influence of different emulsifying agents was investigated with coconut oil emulsified with soya bean phosphatide, purified cerebroside, gelatin-P-20, Demal-14 or Triton-WR-1339. At intervals of 5, 20 and 60 min. and thereafter at hourly intervals after the injection of the emulsion venous blood was withdrawn and the blood fat was estimated turbidimetrically.

The injection of fat emulsion brought about high blood fat values which fell rapidly except when gelatine was used as the emulsifying agent; in all other experiments a straight line resulted when the logarithm of blood fat concentration was plotted against time. The absolute rate of clearance of triglyceride fats did not depend on their chemical composition, but was affected by the emulsifying agent used.—G. A. Garton.

771

SPITZER, J. J. (with BOND, B. D. and GRUNWALD, E. R.) **Influence of protamine on alimentary lipemia.** *Amer. J. Physiol.*, 1953, **174**, 43-45.

[Dept. Physiol., Florida State Univ., Tallahassee.]

Blood fat was raised in dogs weighing 8 to 15 kg. by giving them about 30 ml. cod liver oil. Blood samples were taken for turbidimetric estimation of serum fat. At different intervals after the oil the animals were given 2 to 5 ml. of 1 per cent. aqueous solution of protamine sulphate by intravenous injection.

The injection of protamine caused an increase in the visible fat in serum, starting about 10 to 15 min. after injection and reaching a maximum 30 to 40 min. later. The increase was especially clear when the protamine was administered during the decreasing phase of alimentary lipaemia, though, once visible lipaemia had completely disappeared, protamine had no effect. Other anti-heparin substances, toluidine blue and neutral red, had no influence on visible lipaemia, and it is suggested that protamine causes mobilisation of fat.—G. A. Garton.

772

KRAMÁR, J. and LEVINE, V. E. **Influence of fats and fatty acids on the capillaries.** *J. Nutrition*, 1953, **50**, 149-160. [Dept. Paediat., Sch. Med., Creighton Univ., Omaha, Nebr.]

Groups of weanling albino rats were fed on a fat-free diet or the same diet with 5 per cent. methyl stearate or 5 per cent. maize oil. The capillary resistance and capillary permeability were estimated periodically for at least 150 days.

The capillary resistance of the rats on the fat-free diet or that containing methyl stearate began to decline at about the 50th day of the experiment; the decline, associated with increased permeability, occurred simultaneously with flattening of the growth curve, but before overt signs of fat deficiency appeared. On the diet containing maize oil none of these effects was observed. The capillary resistance was rapidly restored to normal by very small amounts of linseed oil, cottonseed oil or linoleic acid.—G. A. Garton.

773

LÉVY, M. and LEGRAND, J. **De l'utilisation des graisses et des glucides au cours des stéatoses provoquées par des régimes hypoprotidiques-hyperlipidiques. [Utilisation of fats and carbohydrates in steatosis induced by low-protein high-fat diets.]** *Arch. Sci. physiol.*, 1953, **7**, 267-273. [Lab. Physiol. Gén., Sorbonne.]

Rats weighing 150 g. each were fed for 6 weeks on a diet containing 5 per cent. casein and 40 per cent. pork fat. The animals received glucose and sucrose to appetite during a 2-day period 2 days after the beginning of the experiment and again for 2 days at the end. After each 2-day period the R.Q. of the animals was estimated in a Benedict

closed-circuit apparatus. Immediately after each period when carbohydrate was given and the R.Q. was measured, the animals received a mixture of lard and olive oil by stomach tube during a 24-hr. period, after which the R.Q. was again estimated.

No difference was found between the R.Q. of the animals fed on carbohydrate after 2 days on a high-fat diet and after 6 weeks on the same diet; it approximated to 0.70. Similarly, the R.Q. after administration of fat was approximately 1.0 whether the animals had been fed on the high-fat diet for 2 days or 6 weeks.—G. A. Garton.

774

GREENBERG, S. M. and FRAZER, A. C. (with ROBERTS, B.) **Some factors affecting the growth and development of rats fed rancid fat.** *J. Nutrition*, 1953, **50**, 421-440. [Dept. Pharmacol., Med. Sch., Univ. Birmingham.]

Male weanling Wistar rats were fed to appetite for 10 weeks on diets containing different proportions of casein with 10 per cent. soya bean oil, either fresh or rancid. The rancid oil had a peroxide number of 530 to 550 μmol . per g. To each 100 g. oil, fresh or rancid, was added 0.1 ml. ethyl laurate containing 500 μg . diacetyl, in an attempt to overcome any aversion the animals might have to the odour of rancid fat. The effect of whole dried liver, cortisone and several antibacterial drugs was also tested.

A diet containing 10 per cent. rancid oil supported almost normal growth in rats when casein constituted 30 per cent. of the diet; diets containing less protein supported normal growth in animals given fresh, but not rancid, oil, indicating with the latter an increased protein requirement. The only organ weight affected by rancid fat was the small intestine, which showed an increase, possibly owing to increased secretion of mucus.

Supplements of liver appeared to benefit, in proportion to their protein content, the rats given rancid oil. There was no increase in the growth of rats given rancid fat when cortisone or antibacterial drugs were administered.—G. A. Garton.

BOSSHARDT, D. K. and HUFF, J. W. **Nutritional deficiencies in mice caused by stress agents.** *J. Nutrition*, 1953, **50**, 117-127. [Dept. Biochem., Sharp and Dohme, Inc., West Point, Pa.]

Groups of 8 male weanling mice were fed on a low-fat diet containing maize oil 0.5, casein 20, glucose 4, salt mixture 2, cellulose 2, and white dextrin 55.5 parts, with added vitamins A and D, α -tocopherol, naphthaquinone, vitamins of the B group and choline. When 1 to 2 per cent. of succinylsulphathiazole (SST) or 5 to 10 per cent. of 1:20 aqueous extract of liver (Wilson's extract)

was added to the basal diet in place of an equivalent weight of dextrin the mice showed retardation of growth for 7 or 14 days. When both 2 per cent. SST and 2 per cent. liver extract were added the mice lost 0.3 g. in 7 days. These growth retardations could be prevented by increasing the fat content of the diet or adding 10 per cent. defatted cottonseed meal. Similar results were obtained with 1 per cent. SST plus 0.25 per cent. streptomycin or 15 per cent. triacetin and cottonseed meal or cottonseed oil.

When compared with those fed on the basal diet only, groups of mice given 0.16 mg. DL-thyroxine intraperitoneally once a week, or given the basal diet with 1 per cent. iodinated casein, did not grow so well; in contrast, groups given thyroxine, the basal diet and 25 per cent. cottonseed meal or 15 per cent. cottonseed oil grew better, as did also mice given 25 per cent. cottonseed meal or 15 per cent. cottonseed oil without thyroxine.

This suggested that the basal low-fat diet was not fully adequate for maximum growth of young mice and that young weanling mice required in their diet either long-chain fatty acids or a substance necessary for lipid synthesis. This was present in defatted cottonseed meal or was synthesised by intestinal organisms susceptible to SST.—J. M. Naftalin.

GUSTAFSON, G., STELLING, E. and BRUNIUS, E. **Experimental dental caries in golden hamsters—experiments with dietary fats having different contents of unsaturated fatty acids.** *Brit. Dent. J.*, 1953, **95**, 124-125. [Dept. Dent. Histopathol., Dent. Sch., Malmö.]

Cocoa fat with a low, olive oil with a medium and poppy seed oil with a high content of unsaturated acids were each incorporated at the 7 per cent. level in a purified diet for 323 weanling golden hamsters. Mortality was high and after 110 days the groups became too small to continue, but up to that time no difference in rate of growth existed between the groups and none was found in the incidence of caries.—D. Harvey.

KLEIBER, M., BLACK, A. L., BROWN, M. A. and TOLBERT, B. M. **Propionate as a precursor of milk constituents in the intact dairy cow.** *J. Biol. Chem.*, 1953, **203**, 339-346. [Coll. Agric., Univ. California, Davis.]

With the apparatus and technique previously described (Absts. 1470, 2626, Vol. 22; 729, Vol. 23), the distribution of ^{14}C after injection of sodium propionate labelled in positions 1 or 2 was studied. The amounts injected ranged from 9 to 12 μC . of ^{14}C per kg. bodyweight, 2 cows receiving the 1- ^{14}C and 2 the 2- ^{14}C salt. With the first 2 cows the specific activity of ^{14}C in the expired air reached a maximum in 3 to 5 min., and with the second 2 cows in 12 to 15 min. after the injection. Only 30 per cent. of the ^{14}C from the carboxyl group and less than 10 per cent. of the 2- ^{14}C transferred from the propionate to lactose passed through the carbon pool of the cow. Of the ^{14}C injected as 2- ^{14}C propionate over 7 per cent. appeared in the lactose, about 2 per cent. in the casein and 1 per cent. in the fat of the milk during 2 days after the injection. For 1- ^{14}C propionate the corresponding values were 4, 1 and 2 per cent.

THIN, C. and ROBERTSON, A. **Biochemical aspects of ruminant ketosis.** *J. Comp. Pathol.*, 1953, **63**, 184-194. [Dept. Hyg. Prevent. Med., Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

The partition of ketone bodies in blood, milk, urine and rumen liquor of cows was studied by the analytical methods reported in Abst. 1548, Vol. 22. In normal healthy cows only β -hydroxybutyric acid was found in these fluids. In samples from 89 animals with bovine ketosis of varying severity, total ketones were much higher in all fluids than in normal animals. When total ketone bodies were above 60 mg. acetone per 100 ml. blood, acetone formed 42 and 50 per cent. of the total ketone bodies in blood and milk, respectively. In the urine samples of β -hydroxybutyric acid and acetoacetic acid were the main components, and in rumen liquor isopropanol. When total blood ketones were from 10 to 30 mg. acetone per 100 ml., β -hydroxybutyric acid was the chief constituent in blood, milk and rumen liquor, but was exceeded by acetoacetic acid in urine. In 15 cows with pregnancy toxæmia, in which the total ketone bodies in the blood amounted on the average to 67.87 ± 9.45 mg. acetone per 100 ml., β -hydroxybutyric acid accounted for just over 80 per cent. of the total.—W. Godden.

ENGEL, F. L. and HEWSON, K. **Fatty acid and ketone metabolism during hemorrhage and shock in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 608-611. [Dept. Med., Duke Univ., Durham, N.C.]

Male albino rats were fasted for 24 hr.; shock was then induced, under light anaesthesia, by cutting the tails and allowing haemorrhage

equivalent to 2.5 per cent. of the bodyweight to occur in 1 hr. The animals were under observation for 3 to 5 hr., during which blood samples were taken for ketone body and amino-N estimation. Another group of rats were treated similarly, except that adrenalectomy was performed 4 or 5 days before bleeding, and each animal received 0.5 mg. deoxycorticosterone acetate. Animals which showed an increase of less than 3 mg. per cent. in plasma amino-N 3 to 4 hr. after bleeding were classed as showing sublethal haemorrhage, those which showed a greater increase were considered to be in haemorrhagic shock.

While fasting control rats showed the expected progressive rise in blood ketones, all the animals with haemorrhage showed a reduction; adrenalectomised animals behaved similarly.

When an intravenous infusion of Na octanoate was given 2.5 hr. after haemorrhage, rats with sublethal haemorrhage showed a normal increase in blood ketones, but those in haemorrhagic shock showed considerably lower ketone levels.

COCHRANE, G. C., MICHAELS, G. D. and KINSELL, L. W. (with CAWLEY, G., COELHO, M., FUKAYAMA, G., OLSON, F. and SMYRL, S.) **Dietary modifications of plasma cholesterol and phospholipid levels in diabetic patients. The effects of mixed diets high in vegetable fat.**

N.A. and R., January 1954

J. Clin. Nutr., 1953, **1**, 295-298. [Inst. Metabol. Res., Highland Alameda County Hosp., Oakland, Calif.] Spanish summary.

Replacement of animal fat by vegetable fat in high-protein, high-fat diabetic diets resulted in rapid decreases in plasma cholesterol and phospholipins in 5 diabetic patients and in 1 patient with familial hypercholesterolaemia. The effect of the vegetable fat diet was not attributed to low cholesterol intake, since a gradual but substantial fall in plasma lipids occurred in a diabetic patient given vegetable fat in addition to a diet high in animal fat.—F. C. Aitken.

BUGNARD, L., CHEVALIER, F. and COURSAGET, J. Utilisation du cholestérol- C^{14} pour l'étude de l'absorption et de l'excrétion intestinale du cholestérol chez le rat. [Use of ^{14}C -cholesterol in the study of absorption and intestinal excretion of cholesterol in the rat.] *J. Physiol., Paris*, 1953, **45**, 413-419. [Lab. Isotopes, Groupe Hosp. Necker-Enfants Malades, Paris.]

Rats deprived of cholesterol for 1 to 8 weeks were given daily supplements of 10 mg. ^{14}C -labelled cholesterol for several days. Faeces were collected and stored in ethanol; 24 hr. after the last administration of cholesterol the animals were killed, the blood was removed and the carcass was retained in ethanol. Faecal and carcass cholesterol were then extracted and radio-activity was measured.

Faecal cholesterol accounted for 20 to 25 per cent. of that administered, and 40 to 60 per cent. was found in the carcass. Thus 20 to 35 per cent. of the cholesterol had been destroyed in the intestine or in the tissues.—G. A. Garton.

786

SWELL, L. and FLICK, D. F. Effect of dietary fat and cholesterol on the blood cholesterol level in rats. *Amer. J. Physiol.*, 1953, **174**, 51-53. [Gen. Med. Res. Lab., Veterans Admin. Centre, Martinsburg, W. Va.]

Of 2 groups of rats, previously fed on a stock diet, one received a cholesterol-free diet and the other a diet containing 2 per cent. cholesterol. Each diet contained 25 per cent. lard for 20 days, then for 2 periods, each of 20 days, the lard was replaced, first by oleic acid and then by stearic acid. Before introducing the experimental diets and at intervals thereafter of 1 week or less, blood samples were taken for estimation of free and total cholesterol.

Blood cholesterol rose sharply in both groups of rats on the lard diet, the main increase being in the ester fraction. Oleic acid feeding occasioned a slight fall in total and ester cholesterol in both groups; this continued when stearic acid was

given and was more marked in the group which received cholesterol. It is suggested that a diet containing a high percentage of saturated fatty acids may impair the intestinal absorption of cholesterol.—G. A. Garton.

787

ALTSCHUL, R. Inhibition of experimental cholesterol arteriosclerosis by ultraviolet irradiation. *New Engl. J. Med.*, 1953, **249**, 96-99. [Dept. Anat., Sch. Med., Univ. Saskatchewan, Saskatoon.]

Eighteen rabbits were fed for 90 days on a stock diet; each received daily 0.3 g. pure cholesterol or 0.3 g. cholesterol heated at 300° C. for 30 min., contained in a gelatine capsule. The hair was removed periodically from the backs of the animals to facilitate penetration of the ultraviolet radiation to which they were exposed 3 times weekly for 10 to 60 min. Serum cholesterol was estimated in 14 rabbits at the beginning of the experiment and in all the rabbits at the end. Tissues were taken for histological examination, with particular reference to "cholesterol damage", including the presence and quantity of foam cells in the aortic intima, lipid cushions in coronary and lingual vessels and fat deposition in the adrenal cortex.

It is claimed that ultraviolet irradiation caused partial or complete inhibition of the "cholesterol damage" which could have been expected; serum cholesterol at the end of the experiment showed a slight increase or none in rabbits showing little or no cellular damage.—G. A. Garton.

- PETERSON, D. W., SHNEOUR, E. A., PEEK, N. F. and GAFFEY, H. W. **Dietary constituents affecting plasma and liver cholesterol in cholesterol-fed chicks.** *J. Nutrition*, 1953, **50**, 191-201. [Dept. Poultry Husb., Coll. Agric., Univ. California, Berkeley.]

The basal diet was the same as that previously reported (Abst. 647, Vol. 23) except that it contained 2 per cent. alfalfa meal instead of an equal amount of barley. All other additions were made at the expense of barley. The diet contained, by analysis, 0.05 per cent. cholesterol, 0.02 other sterols and 3.0 crude fat. Single-Comb White Leghorn chickens were given the experimental diets at 2 or 3 weeks of age. Pooled samples of plasma from 3 birds were analysed each week for total cholesterol. In some experiments post-mortem liver samples, after 4 to 6 weeks of the experimental diet, were analysed for cholesterol.

Inclusion of 1 per cent. cholesterol with 4 per

cent. cottonseed oil in the diet caused high cholesterol levels in plasma and liver. When the cottonseed oil was omitted there was only a moderate increase in plasma cholesterol. Soya sterols inhibited the rise in plasma and liver cholesterol, the optimum ratio for inhibition being 2 or 3 of sterols to 1 of cholesterol. Caprates of the sterols were ineffective; cholesteryl caprate did not produce a marked rise in plasma cholesterol and liver cholesterol was relatively low.—F. C. Aitken.

793

- SCHWENK, E. and BAKER, C. F. **Studies on the biosynthesis of cholesterol. 5. C¹⁴-cholesterol in the egg yolk and in the laying hen.** *Arch. Biochem. Biophys.*, 1953, **45**, 341-348. [Worcester Found. Exp. Biol., Shrewsbury, Mass.]

Acetate labelled with ¹⁴C in the carboxyl group was administered to hens by injection subcutaneously, intraperitoneally or directly into the crop gland. Eggs and organs were subsequently examined for the presence of ¹⁴C-labelled cholesterol and other ¹⁴C-containing material precipitated by digitonin.

When the birds were killed soon after administration of the labelled acetate, the ¹⁴C-labelled cholesterol in the body was accompanied by other digitonin-precipitable substances which showed a higher counting rate than the cholesterol; these substances were found also in the faeces. Ninety days after the initial injection, ¹⁴C-labelled cholesterol was still present in the liver and viscera, but was not accompanied by higher-counting material. In egg yolk the higher-counting substances were largely replaced by compounds which were also precipitated by digitonin, but showed a lower counting rate than the accompanying cholesterol or were not radio-active. It is considered that these compounds may, nevertheless, be chemically identical with the higher-counting material, since they may have been formed after all the available ¹⁴C-acetate had been used.—G. A. Garton.

- TOTUSEK, R., PLUMLEE, M. P., PERRY, T. W. and BEESON, W. M. **Absorption and utilization of radioactive charcoal by swine.** *J. Animal Sci.*, 1953, **12**, 611-618. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Radio-active charcoal from hard and soft woods was given by stomach tube to 4 pigs maintained on an adequate ration. At least 58 per cent. of

the activity was excreted in the faeces within 120 hr., but only traces were detected in the urine. The pigs were slaughtered and traces of activity were found in the liver, kidney, heart, blood and muscle. Readily detected amounts were found in the bones. The radio-activity of the separate elements was not estimated, but it was considered that in the bones two-thirds of the activity was due to Ca and one-third to P. It was concluded that certain mineral elements in charcoal are absorbed and utilised by the pig.—T. D. Bell.

ENGFELDT, B. **Biophysical studies on bone tissue. 2. The *in vitro* uptake of radioactive phosphate in normal and Paget bone.** *Acta pathol. microbiol. scand.*, 1953, **32**, 529-533. [Dept. Physical Cell Res., Karolinska Inst., Stockholm.]

Thin slices of bone were cut from the long bones of dogs from 1 to 2 years old, killed 3 hr. after receiving 1 mC. radio-active phosphate per kg. bodyweight. The distribution of the radio-active phosphate was studied by autoradiograph. After several months, when the radio-activity of the bone slices had declined to almost nothing, they were incubated with radio-active phosphate *in vitro* and ground somewhat thinner. It could then be demonstrated by autoradiograph that the distribution of the radio-active P in the bone was exactly the same after application *in vitro* as *in vivo*.

Bone slices were taken at autopsy from a patient with Paget's disease. When they were exposed to radio-active P *in vitro* there was a high uptake of P, particularly in those parts of the resorption cavities where new bone tissue was being laid down. It was concluded that results obtained *in vitro* could be accepted as representative of what would happen *in vivo*.—E. M. Hume.

ACKERMANN, P. G. and TORO, G. **Calcium and phosphorus balance in elderly men.** *J. Gerontol.*, 1953, **8**, 289-300. [Div. Gerontol., Med. Sch., Washington Univ., St. Louis, Mo.]

Mixed diets were given to 8 men of 69 to 88 with a mean age of 77 years, and N, Ca and P balance were measured. For N all were positive except in 1 subject for a short period at the beginning of the investigation. For 7 of the men a regression curve was calculated which indicated that 18.5 mg. Ca per kg. bodyweight daily was required for maintaining Ca equilibrium. The eighth subject, whose data were excluded, had a balance of about -1000 mg. Ca daily when intake was 1100 mg. and about -500 mg. even after the intake was

increased to 2000 mg. Ca daily. His X-ray examination showed evidence of osteoporosis. For P the data for all 8 men were used because the subject whose Ca balance was abnormal showed no similar deviation for his P balance; the amount required to maintain equilibrium was found to be 18.7 mg. P per kg. daily.—D. Harvey.

799

BOGDONOFF, M. D., SHOCK, N. W. and NICHOLS, M. P. **Calcium, phosphorus, nitrogen, and potassium balance studies in the aged male.** *J. Gerontol.*, 1953, **8**, 272-288. [Sect. Gerontol., Nat. Heart Inst., Bethesda, Md.]

Seven men aged between 66 and 83 years were the subjects of 2 sets of studies. In the first the diets of 3 contained 107, 859 and 1543 mg. Ca in the 3 periods, all derived from the food; in the second the intakes for 5 subjects, one being re-investigated, were 1600, 292, 816 and 131 mg. Ca in the 4 periods, and only 131 mg. in each diet was from the food supply, the rest coming from added Ca gluconate. Details are tabulated for balances of N, P and Ca and for blood composition in terms of Ca, P, total protein, albumin, globulin and alkaline phosphatase; the second set gives, also, data for K balances and for K in serum.

The K balance and blood composition were unaffected by changes in Ca intake. On the lowest intake of Ca all Ca balances were negative, between -100 and -200 mg. daily. In 2 subjects who had low urinary excretion of Ca during that period there was evidence, when the intake was increased, of more Ca being excreted by the kidneys. If Ca requirement were considered as the level to maintain equilibrium then about 850 mg. daily appeared adequate. Both protein and P intake were high, 13.7 to 17.4 g. N and 1.1 to 2.0 g. P daily and, from the balance data and their bodyweights, the subjects were concluded to have been building protoplasm during the studies. On X-ray examination 2 showed signs of osteoporosis and, with a high Ca intake, their retention of Ca was not much better, indicating, it is suggested, a defect in the mechanism either for building bone matrix or for incorporating Ca in that matrix. [In table 10 the mean Ca balance for subject G.S. should be 94 and not 150 mg.]-D. Harvey.

800

PATTON, M. B., WILSON, E. D., LEICHSENREING, J. M., NORRIS, L. M. and DIENHART, C. M. **The relation of calcium-to-phosphorus ratio to the utilization of these minerals by 18 young college women.** *J. Nutrition*, 1953, **50**, 373-382. [Dept. Home Econ., Ohio Agric. Exp. Stat., Columbus.]

The basal diet contained 344 mg. Ca and 766 mg. P and was given in unsupplemented form or

with additions of 600 or 1200 mg. Ca, each without or with further additions of 300 or 600 mg. P. The extra Ca and P were from CaCO_3 , Ca phosphate, Na phosphate or Na glycerophosphate and Ca : P ratios ranged from 1 : 3.97 to 1 : 0.50. Mean balances ranged from - 46 to + 196 mg. Ca and from - 64 to + 86 mg. P daily. When Ca intake was maintained at any level and P was increased there was no increase in Ca retention, and in P retention there was an increase only when Ca was 900 or 1500 mg. and P intake was 1400 mg. Conversely, when Ca was increased and P was constant there was a significant increase in Ca retention at each level of P, but no effect on P retention.

The indications were that the balances were more closely related to the actual intakes of Ca and P than to the ratios existing between them.

D. Harvey.

801

LEVENSON, S. M., ADAMS, M. A., ROSEN, H. and TAYLOR, F. H. L. **Studies in phosphorus metabolism in man. 3. The distribution, exchange and excretion of phosphorus in man using radioactive phosphorus (P^{32}) as a tracer.** *J. Clin. Invest.*, 1953, **32**, 497-509. [U.S. Army Med. Nutrit. Lab. 9937 TSU-SGO, 1849 W. Pershing Rd., Chicago 9, Ill.]

For earlier work see Abst. 63, Vol. 20.

After a 12-hr. fast, healthy adult males who had been on normal diets received injections of 100 to 200 μC . P^{32} as $\text{Na}_2\text{H}^{32}\text{PO}_4$ into a vein; blood and urine samples were collected at intervals. Some subjects received in addition injections of 25 g. glucose or 0.1 unit insulin per kg. bodyweight 1 hr. after the phosphate injection.

Most of the labelled P left the blood within a few minutes after injection, indicating a very rapid transepillary movement of phosphate. After this initial rapid decrease the rate of disappearance fell. The amount in the red cells increased rapidly in the first 10 or 20 min. and then remained almost constant. Both glucose and insulin accelerated the movement of P^{32} out of the plasma. For 6 subjects the excretion of P^{32} in urine during 1 to 7 hr. after injection averaged 0.8 per cent. of the injected P^{32} per min. It is calculated that the rapidly exchangeable body "phosphorus pool" was about 1.2 g. and that this was turned over about 10 times daily under the conditions of this study. Four hr. after the injection about 95 per cent. of the P^{32} in the plasma was present in inorganic form, the remainder being almost entirely in the acid-insoluble organic form. At peak uptake about 85 per cent. of the P^{32} in the red cells was in inorganic form, but there was a gradual shift from inorganic to organic, so that at 120 hr. after injection about 30 per cent. was in organic form.

W. Godden.

802

MINDER, W. and GORDONOFF, T. **Versuche zur Calcium-Proteinbindung im Blutserum. [Experiments on the binding of calcium to protein in blood serum.]** *Arch. exp. Pathol. Pharmacol.*, 1953, **219**, 485-490. [Radiuminst., Berne.]

Previous experiments (Title 2475, Vol. 22) in which Ca lactobionate labelled with ^{45}Ca was injected into rabbits showed that almost all the ^{45}Ca was precipitated along with the proteins by ethanol. This is confirmed in the present paper with labelled CaCl_2 solution added to human serum *in vitro*. Further experiments with blood taken from a rabbit 5 and 30 min. after injection of labelled Ca lactobionate and fractionated by Cohn's method, and with blood to which labelled Ca lactobionate was added *in vitro* after fractionation, suggested that the Ca rapidly removed from the blood is bound mostly to albumin and to a small extent to α -globulin, and the rest of the Ca to β - and γ -globulin.—W. M. Deans.

803

MÜLLER, E. R. **Zur Frage der Bindung des Calciums im Serum. [On the binding of calcium in serum.]** *Naturwissenschaften*, 1953, **40**, 442. [Med. Klin., Univ. Cologne.]

Blood obtained by heart puncture from rats and mice from 3 hr. to 1 day after they were given CaCl_2 labelled with ^{45}Ca by mouth was subjected to electrophoresis on paper at pH 7.42 and the distribution of radio-activity was followed by Geiger Müller counter.

All the activity was found to be associated with Ca ions, none with serum protein fractions. Similar results were obtained when ^{45}Ca was added to human serum *in vitro*.

It was concluded that the binding of non-ionic Ca, probably to serum protein, is reversible. This agrees with the results of cation exchange experiments by Klement *et al.* (*Naturwissenschaften*, 1953, **40**, 246).—W. M. Deans.

804

VISEK, W. J., MONROE, R. A., SWANSON, E. W. and COMAR, C. L. **Determination of endogenous fecal calcium in cattle by a simple isotope dilution method.** *J. Nutrition*, 1953, **50**, 23-33. [Univ. Tennessee-Atomic Energy Commission, Oak Ridge.]

Three non-pregnant lactating dairy cows and 2 yearling steers were given ^{45}Ca intravenously on 10 successive days. The specific activity of faecal Ca and blood Ca were estimated 4, 5, 6, 7 and 8 days after the last injection and the endogenous faecal Ca was calculated from these data on the assumption that endogenous faecal Ca and total

faecal Ca are in the same ratio as the specific activities of blood Ca and faecal Ca.

The endogenous faecal Ca of the lactating cows was about 7 g. and that of the steers about 4 g. daily. These quantities were not significantly altered by raising the intake of food Ca from normal to high.—R. Hill.

CLARK, R. **A study of the water-soluble phosphate concentration of the ruminal contents in normal and phosphorus deficient animals.** *Onderstepoort J. Vet. Res.*, 1953, **26**, 137-140. [Onderstepoort Lab.]

A comparison of the concentration of phosphorus in the saliva of sheep, goats, cattle, horses and dogs with that in the blood showed that all the ruminant species and, to a less extent, the horse concentrated P. This was most marked with sheep. The concentration of P in the rumen of sheep was less than that of the saliva, but there was no difference between the P concentrations of the rumen in sheep on normal diet and P-deficient sheep, although in the latter both blood and salivary P were reduced. This was true also for normal and P-deficient cattle. Most of the P was absorbed from the small intestine in cattle; the concentration does not fall until below the duodenum.—A. T. Phillipson.

807

LIU, C. H. and McCAY, C. M. **Studies of calcium metabolism in dogs.** *J. Gerontol.*, 1953, **8**, 264-271. [Nutrit. Lab., Animal Husb. Dept., Cornell Univ., Ithaca, N.Y.]

Experiments with young dogs showed that between 14 and 20 weeks of age there was a fall in the percentage of Ca retained from the diet and that when Ca intake was low the balance might be negative. A diet was devised which provided only 4 to 8 mg. Ca per kg. daily. When this was given to dogs between 6 and 25 weeks of age all balances were negative and there was no particular age at which losses were at a minimum. Young dogs were found to retain Ca as well from CaSO_4 as from milk.

Experiments with old dogs of 6 to 15 with mean age 9 years, with intakes from 8 to 477 mg. per kg. daily, showed difficulty in maintaining equilibrium when less than 86 mg. Ca was supplied. For them there was evidence that a diet with 40 per cent.

fat caused a greater loss of Ca than one with 5 per cent. fat and that exercise had a slight favourable influence on Ca retention.—D. Harvey.

FOURNIER, P. **L'absorption du calcium chez le rat adulte. 3. Influence de l'état initial de l'animal. [Absorption of calcium by the adult rat. 3. Effect of the initial state of the animal.]** *C.R. Acad. Sci.*, 1953, **236**, 2537-2539.

For previous work see Abst. 2317, Vol. 21.

Adult male rats in 2 groups of 6 received, for 2 days or 3 weeks, a diet providing not more than 0.01 per cent. Ca and then a supplement of 1 per cent. CaCO_3 and 1 per cent. TiO_2 , replacing starch. The TiO_2 served as a marker for calculation of the coefficient of absorption of Ca. After only 2 days of Ca deprivation mean Ca absorption was 7 mg. daily, and this remained constant. In the other group the mean absorption was 36 mg. on the first day of Ca supplementation and decreased until the seventh day, when it reached the constant level of the first group. This pronounced but brief increase in Ca absorption suggests rapid re-mineralisation of insufficiently calcified bone.—D. Duncan.

SUR, B. K. and SUBRAHMANYAN, V. **Availability of calcium in lucerne and its value in nutrition.** *Indian J. Med. Res.*, 1952, **40**, 481-486. [Central Food Technol. Res. Inst., Mysore.]

At weaning 28 rats were divided into 4 groups; those in one group were killed and found to contain 0.7 ± 0.006 g. Ca per 100 g. bodyweight. The other 3 groups received diets in which the content of 0.34 per cent. Ca was provided by whole milk powder, dried alfalfa or dried amaranth. These rats were killed after 4 weeks, and Ca intake and retention were estimated. The utilisation factor for Ca from whole milk powder was 0.81 ± 0.023 , from alfalfa 0.76 ± 0.022 and from amaranth 0.14 ± 0.049 . The percentages of Ca in the body were 0.88 ± 0.014 , 0.84 ± 0.008 , and 0.66 ± 0.05 , respectively. Rats on the amaranth diet made poor growth, and their food intakes decreased during the last 2 weeks.—D. Duncan.

NAKAJIMA, T. and OTSUKA, J. [On the influence of calcium citrate upon calcium metabolism.] *Bull. Nat. Inst. Agric. Sci., Chiba* [G], 1953, No. 6, 21-27. In Japanese: English summary.

On a diet of unpolished rice with supplements of sodium citrate, calcium citrate or calcium carbonate, female albino rats on the calcium citrate supplement showed the greatest growth and Ca deposition in bone. In rabbits on a rice- and wheat-bran diet with a supplement of sodium citrate the retention of Ca was greater than with a supplement of either sodium carbonate or citric acid. This effect was attributed to the Na ions. With a supplement of calcium citrate the amount of Ca in bone was greater than in animals receiving calcium carbonate. It is suggested that calcium citrate is a better supplement to a Ca-poor ration than calcium carbonate. (From summary.)

TOMLIN, D. H., HENRY, K. M. and KON, S. K.
Autoradiographic study of growth and calcium metabolism in the long bones of the rat. *Brit. J. Nutrition*, 1953, **7**, 235-252. [Dept. Phys., Univ. Reading.]

Rats received a high-Ca diet for 30 days and then a low-Ca diet containing radio-active Ca for up to 113 days. Groups of rats were killed at intervals of about 2 weeks. In a second experiment rats were given the high-Ca diet for 27 days, then half received the high-Ca diet and the others the low-Ca diet. Radio-active Ca was given to these rats from 27 to 107 and from 218 to 301 days and groups of animals were killed at intervals of about 15 weeks.

Autoradiographs were prepared of longitudinal sections of humerus and femur from these animals, and specific activities of different parts of the bones were derived from optical density measurements made with a microphotometer. About 24 per cent. of the Ca in cortical bone was exchange-

able, and this amount was exchanged in about 90 days.

Growth and remodelling by deposition and resorption in different parts of the humerus and femur were described from the autoradiographs.

The low-Ca diet allowed less growth in length and there was difference in the development of the distal diaphysis of the femur. The diameter of the shaft was reduced but normal cortical thickness was maintained.—R. Hill.

KARCHER, H. Der Calcium- und Phosphorstoffwechsel bei der normalen und gestörten Knochenbruchheilung sowie in frischen und konservierten Transplantaten. Ein Nachweis mit den radioaktiven Isotopen P^{32} und Ca^{45} . [Calcium and phosphorus metabolism in normal and pathological healing of fractures and in fresh and preserved transplants, demonstrated with the radio-active isotopes ^{32}P and ^{45}Ca .] *Langenbecks Arch. klin. Chir.*, 1953, **275**, 1-49. [Chirurg. Klin., Univ. Heidelberg.]

The uptake of ^{45}Ca and ^{32}P and their spatial distribution at different stages of healing were studied by 1600 measurements with a counter and 100 autoradiographs with rats whose upper or lower leg bones or metatarsi had been fractured. The animals received an intraperitoneal injection of ^{32}P as sodium dihydrogen phosphate or of ^{45}Ca as Ca lactate at the time of the fracture.

In the first 3 days after fracture the ^{32}P content of the fractured bone was lower than that of the control in the opposite limb, but from the fourth day there was a rapid rise in deposition which, in the upper and lower leg bones, attained a maximum 9 to 11 days after fracture. The uptake of ^{45}Ca followed the same course but was slightly delayed, maximum values being attained 13 to 15 days after fracture. Deposition of the isotopes proceeded for about 4 days longer in the upper than in the lower leg bones. Thereafter the isotope content decreased slowly but was detectable even after 50 days. Metabolic activity of the fractured as compared with the control bone was high both close to the fracture and in the end sections of the bone. An examination of the whole skeletons of some animals during the healing period gave no clear evidence of any general rise in Ca and P metabolism.

In bones with retarded healing of fractures there was a marked reduction of isotope content compared with that of bones healing normally, owing probably to a disturbance in formation of the organic matrix, not to any lack of minerals.

Tests of substances, such as sex and other hormones and certain vitamins, frequently recommended for use as promoters of fracture healing did not show increased deposition of isotopes or

any influence on the bone metabolism if the animals were maintained on an adequate, well-balanced diet.

Experiments with dogs in which fresh bone transplants from another limb were made on to a fractured leg bone showed an increased uptake of ^{32}P in the transplant commencing on about the 20th day after fracture and lasting until the end of the fourth month. The simultaneous building up and breakdown processes in the transplant were clearly seen in radioautographic pictures. The ^{32}P uptake was less in homoplastic than in autoplastic transplants. Preservation of transplants under sterile conditions at 0°C . for 90 days or more before fixation to bone or implantation under the skin resulted in reduced uptake of ^{32}P , but the difference between the two types of transplant was less.—W. Godden.

816

NAKAJIMA, T., ŌMORI, S., ŌTSUKA, J., NOZAKI, H. and NAGAHATA, S. [Phosphorus metabolism in rabbits suffering from so-called osteomalacia.] *Bull. Nat. Inst. Agric. Sci., Chiba [G]*, 1953, No. 6, 37–42. In Japanese; English summary.

Three groups of rabbits were used: (1) showing osteomalacia on a diet of rice- and wheat-bran, (2) a healing group receiving a supplement of calcium citrate, and (3) a control group on the bran diet with calcium carbonate. About $30\ \mu\text{C}$. ^{32}P were given orally to all groups and radioactivity in the bones, urine, whole blood P and serum inorganic P was estimated at 12 or 24 hr.

Compared with groups 2 and 3, group 1 excreted relatively large amounts of ^{32}P in the urine, its specific activity decreasing with time. There was a marked increase in the deposition of P in the bone at the healing stage. Changes in radioactivity in blood P and serum inorganic P are discussed. (From summary.)—J. S. Thomson.

SATO, T. Effects of parotid gland extract upon calcification of dentin of rabbit. *Gunma J. Med. Sci.*, 1953, 2, 183–185. [Dept. Maxillo-stomatol., Sch. Med., Gunma Univ., Maebashi.]

An extract of parotid gland was given to rabbits in a single injection of 5 or 10 mg. per kg. intravenously, or of 15, 25 or 50 mg. per kg. subcutaneously. The effect on dentine formation was studied by marking the time of injection by intravital staining with lead and later examining the regularity of intensity of staining with haematoxylin. The extract was found to have an effect both quantitative and qualitative, irrespective of the route. Small doses accelerated dentine formation, medium doses first accelerated but later slowed formation and large doses hindered it.—D. Harvey.

JOWSEY, J. R., OLIVER, W. F., MAW, W. A. and COMMON, R. H. Observations on the mineral metabolism of pullets. 10. The effects of gonadal hormones on retention and turnover of calcium by the skeleton. *Canad. J. Agric. Sci.*, 1953, 33, 216–224. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

Immature pullets which had received injections of androgen, oestrogen or both during a Ca balance experiment (Abst. 4700, Vol. 23) were given radioactive Ca in food and were killed 24 hr. later.

Net gain of Ca by the skeleton and turnover of skeletal Ca were both increased to a highly significant degree by oestrogen and androgen together. Ca uptake by the skeleton was decreased by oestrogen and turnover was increased by androgen.

The possible reactions involved in the interaction of oestrogen with androgen are discussed in the light of evidence obtained in this and in previous experiments.—R. Hill.

DUNCAN, L. E. (with PONDER, K.) Effect of edema and dietary sodium on efficacy of sodium removal by cation exchange resin. *Amer. Heart J.*, 1953, 45, 802–808. [Sect. Gen. Med., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Two patients who had congestive heart failure with oedema and 1 normal subject were studied. With a diet low in Na, less than 40 m. equiv. daily, the patients were given doses of 120 m. equiv. Resodac 3 times daily and uptake of Na by the resin was estimated while oedema persisted.

Diuresis was then induced and when the patients were free from oedema the uptake was again estimated, after which dietary Na was increased to 122 m. equiv. daily for the third estimation. The normal subject had the same amount of resin first with a high-Na diet, 198 m. equiv. daily, and later with a further 300 m. equiv. Na daily by intravenous injection.

While the patients had a low Na intake the uptake of Na by resin, high when oedema was present, decreased with the oedema. When their Na intake was increased the uptake by resin remained low so long as there was no oedema and increased only when an appreciable amount of oedema had returned. In the normal subject, whose extracellular fluid volume was unaffected, the uptake of Na by resin became greater when the Na intake was increased.—D. Harvey.

MACPHEE, I. W. **Some apparent anomalies of potassium metabolism.** *Brit. Med. J.*, 1953, **ii**, 528-531. [Univ. Liverpool.]

Experimental and clinical contributions to the literature on K deficiency and excess are reviewed. Clinical states of K deficiency are considered, especially those in which there is urinary loss of K. The mechanism leading to such loss in widely different conditions is not fully understood. Diagnosis of K deficiency is hampered by the fact that serum K may be normal while there is considerable cellular K depletion. Electrocardiographic evidence is helpful. Signs of K intoxication are directly related to extracellular K concentrations, and in parenteral K therapy for K deficiency serum K should be kept under observation throughout treatment.—F. C. Aitken.

KUNKEL, H. O., BURNS, K. H. and CAMP, B. J. **A study of sheep fed high levels of potassium bicarbonate with particular reference to induced hypomagnesemia.** *J. Animal Sci.*, 1953, **12**, 451-458. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Thirty adult Rambouillet ewes weighing from 70 to 100 lb. were provided for a pre-experimental period of 3 weeks with a basal diet of cottonseed hulls 50, ground milo grain 30 and soya bean meal 20 per cent. This diet, supplemented with vitamin A, was given at a rate of up to 4 lb. daily, with free access to a mixture of salt and bonemeal. The diet of 22 of the ewes was then altered to include 5 per cent. added K as the bicarbonate. Other differences in treatment of the 22 ewes did not influence the main effects on blood as shown by analyses made after 12, 48 and 62 days on the high K intake. After 62 days mean serum Mg among the high-K ewes was 1.84 mg. per 100 ml. (S.D. 0.24) compared with 2.65 (S.D. 0.21) among controls still receiving the basal diet. The high-K diet had no significant effect on serum Ca, K, Na or total protein. There was no evidence of clinical Mg deficiency, although a transient mild hypersensitivity (increased excitability and polypnoea on exertion) was noted after 48 days in a group receiving a low-salt, high-K diet. Feed intake and rate of gain were decreased by the incorporation of KHCO_3 in the diet.—A. N. Worden.

Electrocardiographic observations on rabbits in which shock had been induced by intraperitoneal injections of veratrine showed that the changes accepted as typical for low blood K were found also associated with high blood K. Thus plasma K has no direct influence on the electrocardiographic changes and such changes cannot give a sure indication of the necessity for therapeutic administration of K.—M. B. Richards.

831

MUNTWYLER, E., GRIFFIN, G. E. and ARENDS, R. L.
Muscle electrolyte composition and balances of nitrogen and potassium in potassium-deficient rats. *Amer. J. Physiol.*, 1953, **174**, 283-288. [Dept. Biochem., State Univ. New York Coll. Med., Brooklyn.]

Mature male rats were fed on diets deficient in K or protein or both. Liveweight changes, N and K balances and the electrolyte composition of plasma and skeletal muscle were studied.

In the absence of K, growth and N retention were reduced, indicating disturbed N metabolism; skeletal muscle contained less K and more Na than normally. When both K and protein were low the disturbance in N metabolism was more serious, but the electrolyte composition of muscle was normal.

Re-feeding with protein after a period of low dietary K and protein did not improve N metabolism, but a rapid fall in muscle K took place, and it was calculated that the amount lost from muscle was greater than that lost from the body as a whole; redistribution of K had apparently taken place.—R. Hill.

CANNON, P. R., FRAZIER, L. E. and HUGHES, R. H.
Sodium as a toxic ion in potassium deficiency. *Metabolism*, 1953, **2**, 297-312. [Dept. Pathol., Univ. Chicago, Ill.]

Adult rats depleted with low-protein diets and afterwards subjected to protein repletion on diets devoid of K developed the myocardial lesions characteristic of K deficiency. The severity of the lesions increased with Na intake and their development could be prevented, even in prolonged K deficiency, by a low-Na diet. NaCl was rapidly and lethally toxic in animals suffering from severe K depletion, and it is suggested that this toxicity may be a consequence of the reciprocal intracellular relationship of Na and K. The cardiac lesions which developed in rats given a low-K high-Na diet differed considerably from the so-called K-deficiency necroses. It may be that under conditions of K depletion the excessive intracellular accumulation of Na injures the intracellular enzyme activities, initiating coagulative necrosis.

M. B. Richards.

MENEELY, G. R., TUCKER, R. G., DARBY, W. J. and AUERBACH, S. H. **Chronic sodium chloride toxicity in the albino rat. 2. Occurrence of hypertension and of a syndrome of edema and renal failure.** *J. Exp. Med.*, 1953, **98**, 71-80. [Radioisotope Unit, Thayer Veterans Admin. Hosp., Nashville, Tenn.]

For part 1 see Abst. 3270, Vol. 23. The groups of rats used in those experiments were maintained on the high-salt diets until they died or were killed, or for 14 months.

In the third month oedema occurred among rats in the 3 groups eating 7.0 to 9.8 per cent. salt, and by the sixth month 16 of these 90 rats had died or been killed because of oedema or subsequent cachexia. All were found to have spectacular kidney lesions. In a small number which survived only 6 to 9 months, but did not become oedematous, there were also widespread kidney and vascular lesions.

After 14 months nearly all the remaining rats in the 3 high-salt groups and most of those receiving 2.8 and 5.6 per cent. salt had significantly raised blood pressure, and those which were killed showed renal and arterial lesions. The average systolic blood pressure showed a linear relation to the amount of salt in the diet, with coefficient of correlation $+0.91 \pm 0.08$.—D. Duncan.

BURNS, C. H., CRAVENS, W. W. and PHILLIPS, P. H.
The sodium and potassium requirements of the chick and their interrelationship. *J. Nutrition*, 1953, **50**, 317-329. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Chickens from 1 to 18 days old received for up to 4 weeks diets which contained 0.02 to 1.50 per cent. Na and 0.11 to 1.50 per cent. K. Growth was poor and mortality was high when both elements were at low levels, or when there was a wide difference between them, even when the low element was at a level which could, with suitable levels of the other, give good growth without high mortality. When both elements were present at high levels growth was good but not quite maximum.

The Na requirement was found to be between 0.10 and 0.30 and that for K between 0.23 and 0.40 per cent., the higher levels being required when other conditions permitted maximum growth.

The requirement for Cl, 0.06 per cent., was less than equivalent to the Na required.—R. Hill.

FLEMING, H. S. Effect of certain concentrations of fluoride on enamel and dentin as formed in transplants of tooth germs and related studies. *J. Dent. Res.*, 1953, **32**, 469-485. [Dept. Pathol., Sch. Med., Yale Univ., New Haven, Conn.]

Fluorine, as CaF_2 or NaF in drinking water or by injection, was given to guineapigs and mice which had received embryonic tooth germs or lung tissue as intracerebral, intra-ocular or axillary transplants. The effects of F on ameloblasts of incisors were studied also in rats without such transfers. Methylcholanthrene was given to some animals with or without F.

The expected calcification of enamel and dentine after they had been formed in the germs was delayed by F. Ameloblasts failed to keratinise even in the presence of methylcholanthrene. The amounts of F used were considered too small to have ionic effects and were thought to have affected carbohydrate utilisation in cells with high energy requirements and to have interfered with transport of metabolites across the cell membrane. The possibility that fast-growing spontaneous mouse tumours may be similarly influenced by F is being investigated.—D. Harvey.

WADHWANI, T. K. and RAMASWAMY, A. S. Pathological changes in the tissues of rats (albino) and monkeys (*Macaca radiata*) in fluorine toxicosis. *J. Indian Inst. Sci.* [A], 1953, **35**, 223-230. [Sect. Pharmacol., Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Twelve albino rats 5 to 6 weeks old were fed on cottonseed globulin 9, gelatine 4, nitrogen-free starch 65, salts 4, choline hydrochloride in sugar (1:9) 1, cystine in sugar (1:19) 1, and vegetable fat 16 per cent., with vitamins A, D and B complex; half the rats were given, one hour before food was offered, 2 mg. NaF in water by mouth daily for 20 weeks.

Four male monkeys, *Macaca radiata*, were each given at 9 a.m. 50 g. bread, 2 mg. ascorbic acid, and shark oil containing 100 units vitamin A and 30 units vitamin D, at noon 50 g. cake made from wheat flour 61, casein 15, sugar 5, salts 4, and fat 10 per cent., and at 4 p.m. 25 g. groundnuts. NaF , 10 mg. per kg. bodyweight, was given by mouth to 2 monkeys at 8 a.m. for 24 weeks.

Histological study of the fluoride-fed rats and monkeys showed degeneration of the epithelium and atrophy of the glands of the stomach; destruction of the epithelium and lymphocytic infiltration of the duodenum and small intestine; degeneration and necrosis of the tubules and atrophy of the glomerulus of the kidney; centrilobular necrosis of the liver; fibrosis in spleen and lung;

degeneration of islet cells and glandular cells of the pancreas; degeneration and pigmentation of adrenal; atrophy of the thyroid and chromatolysis and fibrosis in the cerebral cortex. No change was observed in the heart muscle, aorta, parathyroid or skin. The changes were more severe in the monkeys than in the rats.—J. M. Naftalin.

STANBURY, J. B. Preliminary studies of iodine metabolism in patients from an area of endemic goitre. *Bull. World Health Organiz.*, 1953, **9**, 183-196. [Dept. Med., Harvard Med. Sch., Boston, Mass.] French summary.

The metabolism of the thyroid was studied in 126 goitrous patients from Mendoza in the Argentine, mostly young and having hyperplastic thyroids. Radio-active ^{131}I was administered daily. The peak concentration in the thyroid was often reached within 6 hr., whereas in normal subjects 24 hr. or more were needed. In iodine-deficient regions or areas of endemic goitre, daily renal excretion was 15 to 40 μg ., compared with 100 to 200 μg . in areas without goitre. Ingestion of a goitrogenic substance hindered the uptake of ^{131}I , prevented its utilisation and increased renal excretion. When thyrotropic hormone was administered with the goitrogen the retention of ^{131}I was still further reduced. The tests which were most helpful for the study of goitre prophylaxis were those in which doses of 150, 500 and 1500 μg . ^{131}I were given daily to different patients. The avidity of the thyroid for ^{131}I diminished as the dose increased and iodine balances became positive. One case of thyrotoxicosis occurred after treatment for 32 days with 1500 μg . daily. In 21 patients the addition of stable iodine (^{127}I) showed little effect on the uptake of ^{131}I until the level of 1500 μg . ^{127}I was reached, when the uptake of ^{131}I was depressed. This meant that the proportion of a dose of ^{127}I which was retained depended on the quantity administered. When more than 5 mg. I was given in a dose most of it was wasted.

TAYLOR, S. **An autoradiographic study of simple goitre.** *Bull. World Health Organiz.*, 1953, **9**, 197-210. [Postgrad. Med. Sch., London.] French summary.

Simple goitre was studied in 60 patients; none showed evidence of toxicity or malignancy and all were clinically euthyroid. They were given 100 μ C. ^{131}I in 100 ml. water to drink while fasting. The ^{131}I was estimated in urine and in the thyroid by Geiger Müller counter. Forty-eight hours after ingestion of the ^{131}I , partial thyroidectomy was performed, usually because of pressure on the trachea or oesophagus. Autoradiographs were prepared and it was found that the areas which were active were the small follicles and that the large follicles were mostly inactive. These autoradiographs showed ^{131}I metabolism at only one stage, and an attempt was made to reconstruct the evolution of the disease from all the material. A diffuse hyperplastic gland seemed to be the initial stage, and it developed into a gland with groups of small active follicles or with one large group of active follicles or a nodule. These active nodules then became haemorrhagic and necrotic and finally completely inactive. It is suggested that either a low I intake or the consumption of goitrogenic substances or both may be the cause of goitre; lack of I is not always the only cause.—B. W. Simpson.

842

MURRAY, M. M. **The effects of administration of sodium iodate to man and animals.** *Bull. World Health Organiz.*, 1953, **9**, 211-216. [Bedford Coll., Univ. London.] French summary.

Toxicity tests with sodium iodate were made to study the feasibility of using iodate instead of iodide for iodising salt, when crude moist impure salt was the only kind available or where environmental conditions caused loss of iodine from the salt during storage. In long-term tests 7 rabbits, 6 weeks old, were given 1 mg. sodium iodate per kg. bodyweight twice weekly by mouth; 2 were killed after 4 months and 5 after 8 months. All had been in good health, ate well and gained weight. Their offspring were given by mouth 1 mg. sodium iodate per kg. bodyweight twice weekly from the age of 2 months; 3 were killed after 5½ months, 2 after 7 months and 2 were still alive after 14 months. All the animals had maintained good health. The long-term tests provided still more conclusive evidence of the safety of using iodate for salt iodisation. No toxic sign was seen in several thousands of sheep which licked iodated salt at the rate of 7 mg. iodate weekly for 5 months. Iodisation with iodate at the level of 1 part sodium iodate in

20,000 parts NaCl means a weekly intake in man of 3.5 mg. sodium iodate for 70 g. salt, or 2.2 mg. iodine, on the basis of a daily consumption of 10 g. salt. The iodine of iodates was taken up by the thyroid gland slightly more slowly than the iodine of iodides. It is not suggested that iodate should be employed universally, but only when there is excessive loss of iodine from salt iodised with iodide.—B. W. Simpson.

IRON AND COPPER

843

BURGIO, G. R. and LO JACONO, F. **La sideremia nell'anemia perniciosiforme del lattante.** [Blood iron in pernicious anaemia of infants.] Modificazioni della transferrina a seguito di somministrazione di preparati di ferro in bambini sani ed emopatici. [Modifications of transferrin after administration of iron preparations in healthy children and children with diseases of the blood.] *Bull. Soc. ital. Biol. sper.*, 1952, **28**, 1948-1950; 1950-1952. [Clin. Pediat., Univ. Palermo.]

Iron was estimated in the serum of 14 infants with megaloblastic anaemia. The values were high, ranging from normal values, taken as from 60 to 90 μg . per 100 ml., to 315 μg . per 100 ml. Unsaturated transferrin also was estimated in the serum of 8 of the babies, and values both above and below the normal were found. When treatment was given with vitamin B₁₂ or folic acid, serum Fe fell to about half within 48 hr. The transferrin values were not modified greatly or consistently.

Fe was injected as colloidal Fe saccharate in a dose of 1 mg. Fe per kg. bodyweight or was given orally as ferrous sulphate, 2 mg. Fe per kg. Serum Fe and unsaturated transferrin were estimated before and after. In 4 normal children aged from 7 months to 7 years, the amount of unsaturated transferrin fell after the injection till sometimes none could be found, whether the Fe was injected or given orally. Tests were made also on 3 babies with Cooley's anaemia and on 5 with hypochromic anaemia. The results were not uniform; in some the effect was the same as in normal babies, but in others the amount of unsaturated transferrin rose.—E. M. Hume.

Quelques données nouvelles sur l'élimination rénale du fer. [1. New data on excretion of iron by the kidney.] 2. Utilisation du radiofer pour l'étude des échanges de fer au niveau du tractus digestif. [2. Use of radio-active iron for studying iron metabolism in the digestive tract.] *Arch. internat. Physiol.*, 1953, **61**, 306-317; 318-322. [Clin. Malad. Enfance, Univ. Liège.]

1. Dogs were narcotised with chloralose and the ureters were cannulated. Labelled ferric citrate was injected intravenously.

There was a pronounced increase in excretion of Fe, directly proportional to the amount injected, during the first few minutes after injection, but after 10 to 20 min. it decreased somewhat and became constant. There was some increase in urine volume, but production of diuresis did not increase Fe excretion. Serum Fe decreased abruptly during the initial excretion and the 2 curves stabilised at about the same time. Rate of excretion thus depended upon serum concentration.

2. The same dogs were killed $1\frac{1}{2}$ hr. after injection of Fe and were perfused with physiological saline. The digestive tract and liver were removed for analysis.

The specific activity was highest in the liver, followed by the duodenum, small intestine, colon and stomach.—D. Duncan.

HAMPTON, J. K. (Jr.) and KAHN, J. B. (Jr.) Uptake and storage of radioactive iron by mouse liver. *Amer. J. Physiol.*, 1953, **174**, 226-230. [Dept. Physiol., Sch. Med., Tulane Univ., New Orleans, La.]

Male mice were injected with radio-active iron, ^{59}Fe , and were killed at specified times afterwards and the livers were analysed. The Fe present was fractionated into haemosiderin-rich, HRF, and ferritin-rich, FRF, fractions and from the latter was obtained a ferritin fraction, FF.

Doses of 10.5 to 104.8 μg . ^{59}Fe were injected into a group of mice and all were killed 15 hr. afterwards. As the dose increased, the proportion of it found in the liver increased, but the ratio

FF : HRF was almost constant at unity, although the ^{59}Fe content of the liver varied from 4.3 to 68.4 μg .

Several groups of mice were given approximately 65 μg . of ^{59}Fe and were killed at intervals from 1 to 48 hr. after injection. The FF : HRF ratio in the liver increased from 0.46 at 1 hr. to a maximum of 1.34 at 11 hr., and remained at this value, at least until 48 hr.—R. Hill.

848

STEVENS, A. R. (Jr.), WHITE, P. L., HEGSTED, D. M. and FINCH, C. A. Iron excretion in the mouse. *J. Biol. Chem.*, 1953, **203**, 161-165. [Dept. Med., Sch. Med., Univ. Washington, Seattle.]

Mice received a normal diet with or without added Fe. Some on the normal diet received additional Fe by intravenous injection. Radio-active Fe was injected intraperitoneally and some animals were killed every 4 weeks thereafter. Radio-active Fe was estimated in the whole carcass and in separate tissues.

The fall in ^{55}Fe in the carcass was similar in "iron-heavy" mice to that in mice with normal body stores. The fall in ^{55}Fe was exponential, and about 50 per cent. was lost in 140 days.

In animals made "iron-heavy" the largest fraction of ^{55}Fe was in the liver, but in those with normal body stores the largest fraction was in the blood.—R. Hill.

849

WYATT, J. P. and HOWELL, J. Experimental induction of iron overload in the rat. 1. Morphological alterations due to dietary siderosis. *Arch. Pathol.*, 1953, **55**, 466-474. [Dept. Pathol., Sch. Med., Univ. St. Louis, Mo.]

Groups of 5 or 10 white male rats of initial weight between 63 and 117 g., average 83 g., were fed to appetite on maize grits and lard, or on Purina chow, each with or without 2 per cent. ferric citrate. Half the rats were castrated. After 72 days half the rats were given a supplement of 0.5 per cent. powdered copper acetate.

Rats fed on maize grits lost weight, becoming grossly emaciated; the addition of Cu acetate led to further deterioration and the rats died. The rats fed on chow and ferric citrate grew less rapidly than those fed on chow alone.

Histologically, at 72 days, in the rats fed on maize grits and ferric citrate, Fe was seen to be deposited at the periphery of the liver lobule, in maximum amounts in the Kupffer cells and to a less extent in the liver cells and histiocytes. Giant cells were occasionally seen. At 128 days Fe was present in the liver cells in all parts of the lobule. The Kupffer cells and giant cells were larger. The addition of Cu acetate to the diet increased Fe

N.A. and R., January 1954

deposition. Castration had no effect on Fe deposition. No necrosis or fibrosis was found. The livers of the rats fed on chow with or without added ferric citrate, or on maize grits without citrate, showed only a little deposition of Fe in the Kupffer cells at the periphery.

In rats fed on diets containing ferric citrate, Fe was found in the macrophages round the malpighian bodies of the spleen, and in the inner core of Fleming's germinal centres of abdominal lymph glands. Small amounts of Fe were occasionally found in the cells of the proximal tubules of the kidney in rats fed on maize grits and Fe.

VAN WYK, J. J., BAXTER, J. H., AKEROYD, J. H. and MOTULSKY, A. G. **The anaemia of copper deficiency in dogs compared with that produced by iron deficiency.** *Bull. Johns Hopkins Hosp.*, 1953, **93**, 41-49. [Lab. Metabol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

A marked difference was found between the anaemias due to Fe and Cu deficiency in dogs. Fe deficiency did not affect the number of red cells, but they were smaller and the concentration of Hb was much reduced; Cu deficiency seriously reduced the number of red cells without reducing Hb concentration. In the marrow there were indications that Cu is essential for maturation and production of normal numbers of red blood cells.

BAXTER, J. H. and VAN WYK, J. J. **A bone disorder associated with copper deficiency. 1. Gross morphological, roentgenological, and chemical observations.**

BAXTER, J. H., VAN WYK, J. J. and FOLLIS, R. H. (Jr.) **2. Histological and chemical studies on the bones.** *Bull. Johns Hopkins Hosp.*, 1953, **93**, 1-23; 25-39. [Lab. Metabol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

1. Young dogs, about 4 weeks old, received a purified diet which contained less than 1 μ g. Cu per g. Control animals received the same diet with 8, 15, or 30 μ g. Cu added per g.

Cu-deficient animals became lame and their bones were deformed or fractured, after 2 to 5 months, but appetite and growth were normal. The clinical signs were always associated with unusually thin cortices, reduced cancellous bone and

wide epiphyseal cartilages, as well as anaemia. Affected animals had low Cu concentrations in blood and liver, but blood Ca, P, phosphatase, and vitamin D were normal. The bone abnormalities were not typical of rickets. Cu therapy improved cortex thickness and increased the amount of cancellous bone in a few weeks.

The skeleton was not affected by Fe deficiency even when the young dogs became severely anaemic.

2. Bones from the Cu-deficient dogs described above were sectioned for histological study and cleaned for chemical analysis.

Microscopic examination showed in more detail the effects which had been described from gross observations. There was severe resorption along the medullary surface of shafts, reduced amount of cancellous bone, and wider epiphyseal cartilages than normal, apparently not accompanied by gross disturbance of calcification. Chemical analysis of dry fat-free bone showed that the ash, Ca, P, and carbonate contents were all normal.

Possible reactions involved in the disturbed metabolism are discussed.—R. Hill.

STARKS, P. B., HALE, W. H., GARRIGUS, U. S. and FORBES, R. M. **The utilization of feed nitrogen by lambs as affected by elemental sulfur.** *J. Animal Sci.*, 1953, **12**, 480-491. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Pair-feeding experiments lasting for 90 days were made with 4 Suffolk and 4 Shropshire wether lambs, of initial bodyweight from 37 to 52 lb. One member of each pair was given a modification of the ration used by Thomas *et al.* (Abst. 2858, Vol. 21), containing 2.46 per cent. N and 0.062 per cent. S. The other received the same basal ration, to each lb. of which was added 3 g. elemental S. The addition of S caused a significant increase in the retention of N ($P = 0.015$) and of S ($P < 0.01$), and an increase in wool growth ($P > 0.10$). The lambs receiving the additional S also came nearer to maintaining their original bodyweight.

The S-deficient lambs showed inappetence, loss of wool, excessive lachrymation, profuse salivation, weakness and cloudy eyes, and eventually died. There were some histological abnormalities of the liver, heart and spleen, but it is possible that these were due to some complication, not to primary S deficiency.—A. N. Worden.

854

HALE, W. H. and GARRIGUS, U. S. **Synthesis of cystine in wool from elemental sulfur and**

sulfate sulfur. *J. Animal Sci.*, 1953, **12**, 492-496. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Two yearling wethers each weighing 120 lb. were provided with a diet of 4 lb. maize silage, 3 g. urea, 6 g. salt with trace minerals, 100 g. cerelose and 100 g. soya bean meal, with 7 g. Na_2SO_4 for one and 7 g. elemental S for the other. After preparatory periods of 69 and 111 days, respectively, the wethers were transferred to metabolism cages and $\text{Na}_2^{35}\text{SO}_4$ and ^{35}S were substituted for the stable isotopes. The radio-activity of the urine from the wether receiving sulphate was higher than that from the wether receiving elemental ^{35}S . Examination of wool samples from an area clipped before the experimental period showed that cystine had been synthesised from both forms and apparently to a greater extent from the sulphate.

DE RENZO, E. C., KALEITA, E., HEYTLER, P. G., OLESON, J. J., HUTCHINGS, B. L. and WILLIAMS, J. H. Identification of the xanthine oxidase factor as molybdenum. *Arch. Biochem. Biophys.*, 1953, **45**, 247-253. [Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

Weanling male rats received for one week a purified 21 per cent. casein diet described by Westerfeld and Richert (Absts. 4940, 4941, Vol. 21) and for a second week the same diet with different fractions of liver residue or the ash of soya bean meal added at the expense of glucose. The rats were then killed and homogenates of small intestine were prepared for estimation of xanthine oxidase activity.

The substance stimulating xanthine oxidase activity was present in the ash of both liver residue and soya bean meal, and similar stimulation was obtained from small amounts of Mo added to the diet as sodium or ammonium molybdate, molybdc or phosphomolybdc acid. The other elements present in liver residue ash were ineffective. The maximum daily requirement is estimated as about 0.2 to 0.3 μg . Mo per rat.—D. Duncan.

857

DE RENZO, E. C. Dietary requirement of molybdenum by the rat. *Naturwissenschaften*, 1953, **40**, 251. [Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

A substance in liver residue which raises the level of tissue xanthine oxidase in the rat was identified as molybdenum. It is suggested that purified diets for the rat should include a supplement of Mo at the rate of 40 μg . per kg. diet. This amount produced a "saturation level" of xanthine oxidase in rat intestine.—R. Hill.

858

RICHERT, D. A. and WESTERFELD, W. W. Isolation and identification of the xanthine oxidase factor as molybdenum. *J. Biol. Chem.*, 1953, **203**, 915-923. [Dept. Biochem., Med. Coll., State Univ. New York, Syracuse.]

The unknown dietary substance previously reported (Absts. 545, Vol. 19; 1980, Vol. 20; 4940, 4941, Vol. 21) as necessary for the deposition and maintenance of normal levels of xanthine oxidase in the liver and intestines of rats has now been identified as molybdenum. Numerous fractions isolated from soya flour were tested and their biological activity was related to their Mo content. All the biological activity of the isolated fractions could be accounted for by their Mo content, since all fractions had the same activity as equivalent amounts of sodium molybdate; the Mo content and biological activity were not affected by ashing; removal of Mo by extraction as its ether-soluble thiocyanate or by precipitation with benzinoxime removed all biological activity.—W. Godden.

(Jr.) **The volume of distribution of inulin, antipyrine, and radiosodium during normal and toxemic pregnancy and during the puerperium.** *Amer. J. Obstet. Gynecol.*, 1953, **66**, 18-26. [Dept. Obstet. Gynaecol., Coll. Phys. Surg., Columbia Univ., New York.]

Simultaneous T 1824, inulin, ^{24}Na and antipyrine space estimations were made on 4 patients with severe and 3 with mild pre-eclampsia, 2 with pathological pregnancy (one with oedema, hydramnios and triplets, and one with severe anaemia), 2 in normal pregnancy and 2 normal non-pregnant women. Repeat estimations were made in the pre-eclamptic patients 9 to 63 days after delivery, when all signs had disappeared. Pre-eclamptic patients were maintained on a low-salt diet. All subjects were studied in approximately basal conditions after an overnight fast. A preliminary trial showed that antipyrine passed the placental barrier freely; the work of others indicates that inulin does not penetrate the amniotic sac and that penetration of Na is variable.

In pre-eclampsia the antipyrine and Na spaces were consistently expanded, but the inulin space was normal and plasma volume changes were "unimpressive". Similar changes were found in the 2 women with pathological pregnancy. The puerperal estimates in pre-eclampsia showed considerable reduction of antipyrine and Na spaces, but much less change in the inulin space. The reduction of antipyrine space correlated well with loss of bodyweight. In normal pregnancy there was a slight increase of inulin space but no striking change in antipyrine or Na space. It is concluded

that excessive storage of water and Na in pre-eclampsia is not confined to the extracellular fluid space.—A. M. Thomson.

Extracellular water and total body water were estimated simultaneously in crossbred lambs by methods employing NaSCN or antipyrine, which are being published in detail elsewhere. The extracellular fluid volume in normal sheep was found to be equal to 30 per cent. of the sheared bodyweight and to be extremely consistent in any individual.

The basal ration employed for the first series of experiments consisted of maize and alfalfa hay, in which the ratio Na to K was 1 to 45. The addition of sufficient KHCO_3 to make this ratio 1 to 82 had a dehydrating effect, there being a resulting Na diuresis. The alternative provision of either NaCl or NaHCO_3 had a hydrating effect, and in a further series of experiments it was shown that the administration of NaCl to lambs on a low Na intake caused a rapid expansion of extracellular fluid volume. The sheep appears to have a particular ability to conserve body Na.

Equations are given for calculating total body Na, total exchangeable Na and extracellular Na from estimated serum Na and extracellular fluid volume.—A. N. Worden.

CASTILLON, L. E., KARON, M., ALTSCHUL, A. M. and MARTIN, F. N. **Preparation of combina-**

tion products of gossypol with glycine and dextrose and their toxicity toward mice. *Arch. Biochem. Biophys.*, 1953, **44**, 181–188. [S. Reg. Res. Lab., New Orleans, La.]

A freshly-prepared combination product of gossypol and glucose, when given to mice by stomach tube, proved more toxic than gossypol itself and as toxic as the isolated pigment glands of cottonseed. The toxicity decreased appreciably on storage. A combination product of gossypol and glycine was not toxic to mice in doses of as much as 12.0 g. per kg. bodyweight, but a physical mixture of gossypol and glycine was as toxic as gossypol. Purified gossypol-glycine, which contains 3.37 per cent. N, does not correspond to any molecular compound of gossypol and glycine, but apparently the substances enter into some chemical combination which alters the pharmacological properties of gossypol. Gossypol-glycine is soluble in water and differs from gossypol in many of its properties.—M. B. Richards.

SERLING, F., MAXWELL, E. S. and OETTINGEN, W. F. v. **Comparative excretion and distribution of C¹⁴-labeled carbonate and formate in large albino rats.** *Amer. J. Physiol.*, 1953, **174**, 33–38. [Nat. Inst. Arthritis and Metabol. Dis., Nat. Insts. Health, Bethesda, Md.]

Eleven adult male rats weighing from 400 to 537 g. received a diet of 10 per cent. dextrose in whole milk. After 10 to 14 days, 6 rats received single intraperitoneal injections of 0.03 to 0.05 mC. ¹⁴C-labelled sodium carbonate and 4 a similar volume of solution containing 0.07 to 0.10 mC. sodium formate. The rats were then placed in closed respirometers for 8 days, receiving the same diet. At the end of the experiment the rats were anaesthetised and tissue samples were removed for analysis.

Recovery of ^{14}C from excreta and tissues was 96 to 101 per cent. in the carbonate group and 92 to 110 per cent. in the formate group. Patterns of excretion and distribution were similar, but carbonate excretion was more rapid and more complete. More than 90 per cent. of the ^{14}C from carbonate was excreted in the first 24 hr., and 80 per cent. of that from formate. At the end of the experiment the percentages excreted were 95 and 90, respectively, and most of this was in CO_2 . Tissue distribution of the remainder was similar in both groups, and is fully described.

D. Duncan.

ZIRM, K. L. and KILCHES, R. Zur Frage der Resorbierbarkeit von wasserlöslichem Blattgrün unter Anwendung eines C^{14} -markierten Chlorophyllins. [The question of absorption of soluble chlorophyll studied with chlorophyllin labelled with ^{14}C .] *Biochem. Ztschr.*, 1953,

324, 241-243. [Forsch. Lab., Lannacher Heilmittel G.m.b.H., Lannach, Styria.]

Groups of white mice which were given by stomach tube a solution of chlorophyllin-Na, labelled with ^{14}C , were killed after intervals of 1½, 16 and 24 hr. Only the small and large intestines at any time showed radio-activity. Another group were kept in a suitable cage and faeces were collected every 24 hr. The radio-activity of the faeces, after showing a maximum value in the first 24 hr., rapidly diminished, but had not completely disappeared after 8 days. This protracted excretion is explained by the mixing of older and fresher intestinal contents in the caecum. The results show clearly that soluble chlorophyll, given to mice by mouth, is not absorbed through the wall of the intestine. The mechanism of the action of chlorophyll is therefore to be sought in the intestine itself.—M. B. Richards.

REID, L. C. Effect of thiourea and thyroxine on oxygen uptake of tissue homogenates. *Arch. exp. Pathol. Pharmacol.*, 1953, **219**, 466-468. [Dept. Surg., Univ. New York.]

The effect of thiourea on oxygen uptake in tissue homogenates from mice and rats was studied by the Warburg technique. In liver, kidney, spleen, brain, gastric mucosa and skeletal muscle, with K succinate as substrate, thiourea decreased O_2 uptake. In 18 experiments with heart tissue, however, there was a small but definite increase in O_2 uptake. When succinate

was replaced by α -ketoglutarate, citrate or malate, for kidney, liver or brain tissue, thiourea again reduced O_2 uptake.

Thyroxine in concentration of at least 3 μg . per ml. increased O_2 uptake by homogenates of liver, kidney or brain and counteracted the depression produced by thiourea.

The possibility is considered that thiourea is not a specific antithyroid drug, but a general depressant.

SADHU, D. P. Physiological significance of lactose in pigeons. *Amer. J. Physiol.*, 1953, **174**, 238-240. [Dept. Physiol., Presidency Coll., Calcutta.]

Of 3 groups of 8 young pigeons receiving whole wheat to appetite, one group received in addition daily for 4 weeks 1 g. glucose, and one group 1 g. lactose. Extracts of brain and liver were then analysed for cerebroside, sphingomyelin, phospholipin and fat, and homogenates of liver and small intestine were used to study lactic dehydrogenase activity.

In the lactose-fed group bodyweight decreased and liver fat and phospholipin were low. Brain phospholipin and cerebroside were slightly above

control levels, but sphingomyelin was much less. With glucose, however, brain cerebroside was significantly reduced and liver sphingomyelin was lower than in the lactose or control group.

Dehydrogenase activity was relatively low in the liver of lactose-fed pigeons, and high in the intestine.—D. Duncan.

KERNER, E. and WESTERFELD, W. W. **Effect of diet on rate of alcohol oxidation by the liver.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 530-532. [Dept. Biochem., State Univ. New York.]

Oxidation of alcohol by liver homogenates was estimated manometrically by O_2 consumption by a procedure designed to indicate alcohol dehydrogenase in the liver.

Young and adult male rats were given chow, 24 per cent. casein, or protein-free diets for 16 or 24 days, and energy restriction was studied by starvation for 7 days or 50 per cent. restriction of chow intake for 14 days.

Alcohol oxidation by liver homogenates was half as great in weanling rats as in adults, but it reached the adult level after 16 days on chow or the high-protein diet. In both adults and young rats the protein-free diet reduced alcohol oxidation to low levels. Starvation of adult rats reduced alcoholic oxidation by about 50 per cent., but partial restriction of chow intake gave only a slight reduction after 2 weeks.—D. Duncan.

HOCH-LIGETI, C. **Influence of low protein diet on distribution of D-amino acid oxidases in rats.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 403-405. [Dept. Pathol., Med. Sch., Univ. Virginia, Charlottesville.]

Three diets, one containing 8.5 per cent. casein, carbohydrates, fats, salts and vitamins, one similar with the addition of 5 μ g. α -oestradiol daily, and a control diet of rat biscuits, were given to groups of rats for 3 or 9 months. The animals were then killed and the oxygen uptake of homogenates of liver or kidney in the presence of DL-alanine or D-aspartic acid was estimated; behaviour towards these 2 substrates was found to be similar.

All the rats on the low-protein diets had enlarged fatty livers; the livers of the male rats receiving oestradiol showed pronounced cirrhosis and some cholangiomas. The D-amino-acid oxidase activity of the kidney was similar for each diet, but the activity of the liver of rats given the low-protein diets was about half that of the controls; oestradiol had no added effect.—C. Warner.

SHEFFNER, A. L. and BERGEIM, O. **The effect of dietary amino acid levels upon the oxidation of L- and D-amino acids by kidney tissue.** *J. Nutrition*, 1953, **50**, 141-148. [Dept. Biol. Chem., Univ. Illinois Coll. Med., Chicago.]

Rats received basal diets with either 10 or 15 per cent. casein and groups of 4 to 6 animals received supplements of DL-methionine or DL-phenylalanine. Each supplement increased the oxidation of L-methionine by kidney slices. D-Amino-acid oxidase activity was greater after the 15 per cent. than the 10 per cent. casein diet; supplementation of the latter, but not of the former, with DL-methionine increased the resulting activity. Succinic dehydrogenase activity of kidney slices was not affected by addition of amino-acids to the 15 per cent. casein diet.—D. Duncan.

SAKA, M. O. and SIPAHIOĞLU, Ü. **Lipolytic activity of liver tissue of rats on a diet deficient in essential fatty acids.** *Amer. J. Physiol.*, 1953, **174**, 49-50. [Dept. Physio-Pathol., Univ. Istanbul, Turkey.]

Rats were fed on fat-deficient diets until arrest of growth, emaciation and scaliness of the feet, tail and skin appeared, usually in about 8 weeks. Other groups of animals were fed for 4 weeks on the same diet, which was then supplemented with arachidonic acid or a mixture of linoleic and linolenic acids. The lipolytic activity of liver homogenates was then estimated by the method of Willstaetter and Memmen (*Hoppe-Seyler's Ztschr.*, 1923, **121**, 1), with tributyrin as substrate.

The lipolytic activity in livers of animals deprived of essential fatty acids was considerably diminished. Arachidonic acid was more effective in re-establishing liver lipase activity than was the mixture of linoleic and linolenic acids.

G. A. Garton.

891

HUMOLLER, F. L. and ZIMMERMAN, H. J. **Relation of choline oxidase activity to dietary fatty livers.** *Amer. J. Physiol.*, 1953, **174**, 199-202. [Med. Res. Lab., Vet. Hosp., Omaha, Nebr.]

Fatty livers were produced in rats by a high-fat, low-choline diet containing, per cent., casein 5, glucose 48, cellulose 2, lard 40 and salt mixture 5, with a vitamin mixture. The rats were killed and choline oxidase activity of liver homogenates was estimated manometrically.

There was a precipitous decline in choline oxidase activity from the first day on which the diet was consumed, but after about a week the decrease became slower. During the first week the increase in liver fat was as rapid as the decrease in choline oxidase, but the increase was maintained and the inverse relationship ceased after this time. When 1.16 mg. or more stearic acid was added to the liver homogenates there was a decrease of choline oxidase activity, especially at pH 6-7. This effect occurred with both normal and fatty livers.

When 10 mg. choline or betaine was injected 2 hr. before death, after 14 days on the high-fat diet, there was no effect on liver choline oxidase activity, or on the endogenous O_2 uptake of the homogenates.—D. Duncan.

The mammary glands of lactating rabbits were homogenised in a buffer solution at pH 7.4. The homogenate was filtered and fractions designated as supernatant, mitochondria and microsomes were separated by centrifuging. The fractions were incubated separately or in combination with ^{14}C -carboxyl-labelled acetate, K oxaloacetate and adenosinetriphosphate.

The supernatant incorporated 5 to 10 times as much acetate into fatty acids as the full homogenate or the mitochondria. When the super-

natant was combined with mitochondria, fatty acid formation was reduced to the lower levels observed with the full homogenate; no fatty acid synthesis was found to occur with microsomes alone.—G. A. Garton.

GEYER, R. P., BOWIE, E. J. and BATES, J. C. **Effect of pyruvate on octanoate metabolism as influenced by potassium and lithium.** *J. Biol. Chem.*, 1953, **203**, 625-628. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

In continuation of earlier work (Absts. 5220, Vol. 19; 3307, Vol. 23) liver, kidney, spleen and heart slices from rats which had been maintained on a stock diet were incubated for 1 hr. with ^{14}C -labelled sodium octanoate in 0.154 M NaCl containing Na_2HPO_4 -HCl buffer; pyruvate was added and sometimes K or Li salts at 77 m. equiv. per litre. Pyruvate decreased octanoate metabolism by liver slices when high concentrations of K or Li were present, the effect being mainly on acetoacetate formation. Acetate or lactate in place of pyruvate, without K or Li, was without effect, but glycerol caused a decrease of acetoacetate formation and an increase in $^{14}CO_2$. Pyruvate decreased octanoate metabolism by kidney slices, and acetate decreased $^{14}CO_2$ formation when the concentration of K in the medium was high. Pyruvate decreased octanoate metabolism by heart but not by spleen.—W. Godden.

898

WIKRAMANAYAKE, T. W., HEAGY, F. C. and MUNRO, H. N. **The effect of level of energy intake on the metabolism of ribonucleic acid and phospholipin in different parts of the liver cell.** *Biochem. biophys. Acta*, 1953, **11**, 566-574. [Dept. Biochem., Univ. Glasgow.] French and German summary.

Adult rats received a protein-free diet at different levels of energy intake for 4 or 11 days before being killed. Some received ^{32}P as inorganic phosphate by intramuscular injection 2, 4 or 18 hr. before death. The livers were perfused with saline and removed, to be separated into cell fractions.

The specific activity of ribonucleic acid (RNA) P in the whole cell increased with increased energy intake. The increase occurred first in the nuclear RNA, but by 4 hr. after ^{32}P injection it was shown in all cell fractions, least in the cell sap. The phospholipin P showed no change in ^{32}P uptake comparable to those in RNA.

Total RNA, protein and phospholipin in the mitochondrial fraction showed little variation with diet, but RNA in the microsomes was considerably reduced by protein-free diet. RNA was increased in microsomes and cell sap by raising the energy intake, whether the diet contained protein or not. Total protein was increased in the microsomes by increasing energy intake at both levels of protein intake, but in cell sap total protein increased only when the diet contained protein. Phospholipin in microsomes and cell sap also showed some influence of diet and the energy intake had more effect when the diet contained protein.

The reasons for the differences in RNA metabolism are discussed.—D. Duncan.

899

DiSTEFANO, V. and NEUMAN, W. F. **Calcium complexes of adenosinetriphosphate and adenosinediphosphate and their significance in calcification *in vitro*.** *J. Biol. Chem.*, 1953, **200**, 759-763. [Div. Pharmacol., Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, New York.]

^{45}Ca was shaken for 3 hr. at 37°C . with solutions of adenosinetriphosphate (ATP) or adenosinediphosphate (ADP) in veronal buffer at pH 7.4, with Dowex 50 cation exchange resin in the Na form. Relatively undissociated Ca complexes were formed, ATP being the stronger complex-forming agent; the dissociation constants for the ATP and ADP complexes were 8.7×10^{-5} and 1.8×10^{-4} , respectively.

Tibial sections from rachitic albino rats were incubated with 0.005 M ATP; hydrolysis of ATP was slow and the total inorganic P liberated at the end of 7 hr. was only 5.6 per cent.

The results are considered to explain the inhibitory effect of ATP on calcification of rachitic bone slices *in vitro*.—A. Iggo.

STEWART, A. G. and BEGG, R. W. **Systemic effects of tumors in force-fed rats. 2. Effect on the weight of carcass, adrenals, thymus, liver and spleen. 3. Effect on the composition of the carcass and liver and on the plasma lipids.** *Cancer Res.*, 1953, **13**, 556-559; 560-565. [Dept. Med. Res., Univ. W. Ontario, London.]

2. Groups of male Sprague Dawley rats of initial weight between 163 and 200 g. had Walker 256 carcinoma implanted in both lumbar regions, and were force-fed with diets high in fat, equivalent to 83 or 60 per cent. of the energy, or in protein or carbohydrate, each as 60 per cent. of the energy. The diet was mixed with water and 20 ml., equivalent to 35 Cal., were given twice daily. Rats without tumour, of similar initial weight, were force-fed on these diets as controls. Two further groups with implants of Walker 256 carcinoma and 2 groups without tumour, fed to appetite on a stock chow diet or on the synthetic diet containing fat as 60 per cent. of the energy, were also studied.

The final bodyweights of the force-fed control rats and the control rats fed on chow to appetite were similar, but significantly less than those of the rats fed to appetite on the high-fat diet. Despite the fact that they ingested the same amount of food, the final bodyweights of the force-fed tumour-bearing rats were significantly greater than those of their controls, but after allowing for the weight of their tumours, about 20 per cent. of their bodyweights, their carcass weights were considerably less with diets containing 83 per cent. fat or

N.A. and R., January 1954

60 per cent. carbohydrate. The final carcass weight of the tumour-bearing rats fed to appetite was less than that of normal rats. Tumour-bearing rats had larger adrenals, livers and spleens and smaller thymuses. Force-feeding did not prevent these changes.

3. As compared with the non-cancerous rat receiving the same amount of food, carcass analysis suggested that the increased bodyweight of the tumour-bearing force-fed rat was due to water. High blood lipids, from 1122 to 5598 mg. per 100 ml. plasma, were found in the tumour-bearing rats; the control values were 214 to 289 mg. per 100 ml. Increased plasma phospholipin and cholesterol accounted for only a small amount of this increase. Tumour-bearing rats had less N and fatty acids in their carcasses, and the loss was diminished, but not prevented, by forced feeding.—J. M. Naftalin.

903

TANNENBAUM, A. and SILVERSTONE, H. **Effect of limited food intake on survival of mice bearing spontaneous mammary carcinoma and on the incidence of lung metastases.** *Cancer Res.*, 1953, **13**, 532–536. [Dept. Cancer Res., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

In 2 experiments C3H female mice fed to appetite on Purina chow were examined at fortnightly intervals for the appearance of spontaneous mammary tumours. The mice developing tumours were then paired according to weight, size and location of tumour. One mouse of each pair was fed on Purina fox chow meal 50, skimmed milk powder 25, maize starch 20, brewer's yeast 3 and partly hydrogenated cottonseed oil 2 per cent., and given 3.6 g., equivalent to 13 Cal., daily (full-fed). The other mouse was given 2.0 g., equivalent to 7.4 Cal., daily (underfed). In a third experiment, planned to examine the incidence of metastases, one mouse of each pair was given Purina meal 1.2 g., milk powder 0.7 g., brewer's yeast 0.1 g. and maize starch 1.6 g. (total 3.6 g.); the other was given 2.1 g. by reducing the starch to 0.1 g. (energy-restricted).

In experiment 1 the full-fed mice survived 83 ± 48 days after the detection of their tumour, and the underfed mice lived 23.8 ± 7.93 days longer. In experiment 2 the figures were 74 ± 4.5 and 16.2 ± 6.61 . Sixty-five per cent. in experiment 1 and 69 per cent. in experiment 2 of the underfed mice outlived their controls. Fewer of the underfed and energy-restricted mice developed additional mammary carcinomas or grossly visible lung metastases. This was most apparent in experiment 3, in which the survivor was killed on the death of its control.

The underfed and energy-restricted mice lost more weight than the full-fed controls.

J. M. Naftalin.

904

TANNENBAUM, A. and SILVERSTONE, H. **The genesis and growth of tumours. 6. Effects of varying the level of minerals in the diet.** *Cancer Res.*, 1953, **13**, 460–463. [Dept. Cancer Res., Med. Res. Inst., Michael Reese Hosp., Chicago 16, Ill.]

For earlier studies in the series see Absts. 630, Vol. 10, 937, Vol. 19 and 1549, Vol. 23.

With a purified diet the mineral intake of mice was varied by additions of Wesson's modification (*Science*, 1932, **75**, 339) of the Osborne-Mendel salt mixture at 2, 4 and 8 per cent. The mineral content of the diet had no significant effect on the incidence of spontaneous mammary cancer or of skin tumours induced by carcinogenic hydrocarbons, their time of appearance or their rate of growth.—D. Harvey.

905

POPPER, H., DE LA HUERGA, J. and YESINICK, C. **Hepatic tumors due to prolonged ethionine feeding.** *Science*, 1953, **118**, 80–82. [Hektoen Inst. Med. Res., Chicago, Ill.]

Female rats were given 0.5 or 0.2 per cent. ethionine in a diet of casein 16, sucrose 75 and maize oil 5 per cent. with essential minerals and vitamins. The methionine content was 0.4 per cent. Nodules of liver cells (hepatomas) or in bile ducts (cholangiofibrosis or cholangiomas) were seen in 8 of 12 rats given 0.5 cent. ethionine for 51 days, in 1 rat given 0.5 per cent. for 77 days and in 2 of 4 given 0.2 per cent. from 87 to 104 days. Of 6 rats for which the 0.5 per cent. ethionine diet alternated with stock diet, 2 showed nodules after 60 and 67 days. Such lesions were not found in rats given 0.2 per cent. ethionine for shorter periods or in controls given the purified diet without ethionine.

The liver histology is described and illustrated with photomicrographs.—F. C. Aitken.

906

LEVY, H. M., MONTAÑEZ, G., MURPHY, E. A. and DUNN, M. S. **Effect of ethionine on tumor growth and liver amino acids in rats.** *Cancer Res.*, 1953, **13**, 507–512. [Chem. Lab., Univ. California, Los Angeles.]

Rats received subcutaneous inoculations of fibrosarcoma or Jensen sarcoma tissue. DL-Ethionine was incorporated into the diet at the 0.25, 0.5 or 1.0 per cent. level, or was injected subcutaneously.

In control rats with food intake restricted to that of tumour-bearing animals ethionine produced early loss of weight, but this did not continue except at very high levels of injected ethionine. In tumour-bearing rats ethionine retarded the growth of the tumours and increased the percentage

which regressed. Necrosis occurred in all the tumours.

There was no significant difference in the percentage of total amino-acids in the liver between normal, tumour-bearing and ethionine-treated rats, but the percentage of free amino-acids increased

in livers of rats bearing large tumours and in all those receiving ethionine in the diet.

There were numerous deaths from ethionine poisoning and probably also from the toxicity of the products of necrosis.—D. Duncan.

METABOLISM OF GROWTH, REPRODUCTION AND SENESCENCE

GROWTH

907

ALM, I. **The long-term prognosis for prematurely born children: a follow-up study of 999 premature boys born in wedlock and of 1002 controls.** *Acta paediat.*, 1953, **42**, Suppl. 94, pp. 116. [Clin. Paediat., Karolinska Sjukhus, Stockholm.] French, German and Spanish summaries.

The persons studied were born in 3 hospitals in Stockholm between 1902 and 1921. The premature boys weighed from 1010 to 2500 g. at birth. The controls were of birthweight over 2760 g. and of comparable social background. Mortality remained considerably higher among the prematures until the children were 2 years old, and it was greater among plural-born than among single-born premature boys. At 20 years of age the mean height and weight of the premature group were significantly less than those of the controls; mean weight 64 compared with 67 kg. The proportion receiving pensions or institutional care because of mental deficiency, spastic paralysis or other conditions possibly related to birth injury was significantly greater in the premature group. The premature, however, were a match for the control group in respect of social adaptation and economic status. A critical review of previous work on this subject is included.—M. S. Fraser.

908

MILLIS, J. **Factors influencing the birth weight of offspring.** *Med. J. Malaya*, 1953, **7**, 168–178. [Dept. Social Med., Univ. Malaya, Singapore.]

In continuation of previous work (Abst. 2775, Vol. 22), data are discussed for 9473 boys and 8976 girls, normal full-term infants born in 1950 and 1951 to Chinese mothers in hospital in Singapore. It is considered probable that the poorer people's diet was adequate in quantity, but low in protein, Ca and some vitamins.

Mean birthweights in 1950 and 1951 were 6.89 and 6.91 lb. for boys and 6.72 and 6.71 lb. for girls; the sex difference was significant. Mean birthweights for 719 boys and 770 girls born to Indian mothers were about 0.4 lb. less. For the Chinese babies mean birthweight increased with parity, the difference for males being significant even beyond the third birth, and with age of mother

when these were considered separately; their interaction is discussed elsewhere (Millis and You, 1953, in the press). There was no seasonal effect, but the climate of Singapore is much the same all the year round.—W. M. Deans.

909

MILLIS, J. **Growth curves of Singapore-born Chinese infants during the first year.** *Med. J. Malaya*, 1953, **7**, 296–304. [Dept. Social Med., Univ. Malaya, Singapore.]

Mean weights in oz. of healthy Chinese infants, 711 male and 665 female, of mothers, mainly from the poorer classes, attending government welfare clinics in Singapore in the years 1949 to 1951, are tabulated and shown graphically for the sexes separately. Weight increase was equal to that of British and American infants during the first 6 months, but less during the second 6 months, so that the difference at 1 year was about 4 lb. The results resembled those of Guy *et al.* (Title 5267, Vol. 7) for Chinese infants in Peiping.

W. M. Deans.

910

SALBER, E. J. and BRADSHAW, E. **Weight of Bantu babies in the first 10 days of life.** *Brit. J. Prev. Social Med.*, 1953, **7**, 154–159. [Inst. Family and Community Health, Durban.]

This study covered 598 full-term healthy Bantu babies born in hospital and breast-fed at approximately 3-hr. intervals with a night feed. For both boys and girls the maximum mean loss of weight was on the 3rd day and amounted to about 5 per cent. of birthweight. Firstborn babies lost more of their birthweight and took longer to regain it than later babies. By the 7th day 48 per cent. of the babies had regained their birthweight and by the 9th day, 59 per cent. This good progress is ascribed to the excellence of Bantu mothers as breast-feeders.—W. M. Deans.

PHILLIPS, H. T. **Some social and ethnic variations in the physique of South African nursery school children.** *Arch. Dis. Childhood*, 1953, **28**, 226–231. [Inst. Family and Community Health, Durban.]

For this study heights and weights of 392 boys and 409 girls, measured at quarterly intervals between the ages of $2\frac{3}{4}$ and $5\frac{1}{2}$ years, and some from $2\frac{1}{4}$ to $6\frac{1}{4}$ years, were extracted from the records of nursery schools in Cape Town (1 white upper-income), Johannesburg (3 white upper-income, 5 white lower-income) and Durban (1 white upper-income, 1 Bantu, above-average urban) for periods ranging from 1936 to 1951. Quarterly means and standard deviations are tabulated.

In the upper-income group boys were as usual taller and heavier than girls of the same age. In the lower-income group, however, girls over $3\frac{1}{2}$ tended to be slightly taller than boys. Among the Bantu the boys were taller, but the girls were heavier; whether this is due to any sex difference in feeding is not known, though it is stated [without details] that the boys had a higher incidence of clinical signs of malnutrition than the girls.

Children of the upper-income group were significantly taller and heavier at all ages than those of the lower-income group, the differences being from 3 to 5 lb. and 2 to $2\frac{1}{4}$ in. for boys and from 2 to $4\frac{1}{2}$ lb. and $1\frac{1}{4}$ to $2\frac{1}{2}$ in. for girls.

White lower-income boys and girls were slightly but not significantly heavier than Bantu boys and girls; they were also taller, and some of the differences were significant.—W. M. Deans.

ROUTIL, R. Über die körperliche Entwicklung von Schulkindern. (An Kärntner Landkindern erhobene Daten und deren Beurteilung.) [Physical development of schoolchildren. Evaluation of data for Carinthian country children.] *Öst. Ztschr. Kinderheilk.*, 1953, 8, 377-395. [Anthropol. Sammlung, Naturhist. Museum, Vienna.]

Tables are given for height and weight of 6365 boys and 6183 girls, aged from 6 to 15 years, from the district of Völkermarkt, Carinthia, in the years since 1948. All data are from school records.

Comparison with figures for 1052 boys and 1053 girls from the same region in 1935-36, for the ages from 7 to 14, showed that in 1948 the mean values for height were 1 or 2 cm. greater for all ages except boys of 12 and girls of 14. Bodyweight also was somewhat greater in 1948. The 1052 boys and 1053 girls from Völkermarkt district were compared with 1370 boys and 1342 girls from the district of Wolfsberg, which included rural and mountain villages. The social conditions of the Wolfsberg children were somewhat better, but they had further to go to school, 19 per cent. walking for over an hour. In both districts intelligence grading was about the same, and girls did somewhat better at school. Children in Wolfsberg were a little taller but not consistently heavier. In some villages development was much

poorer than in others. The height of girls, but not of boys, was unfavourably influenced to a small extent by long distance from school; weight was not affected. Where distance from school was great there were more children in the lowest grade of school performance. The bigger the child, the better the school performance.

A standard of normal height, weight and chest measurement is tabulated for every month of age from 7 to 15 years and 3 months for boys and to 14 years and 4 months for girls. The data were derived from 7753 boys and 7215 girls in the years 1935-38, and include those for Wolfsberg and Völkermarkt, with others for Klagenfurt and Villach and the country surrounding them.

PECKOS, P. S. Caloric intake in relation to physique in children. *Science*, 1953, 117, 631-633. [Dept. Nutrit., Forsyth Dent. Infirmary Child., Boston, Mass.]

To discover whether differences exist in the energy intakes of children of different physiques, 86 subjects were selected from 350 who were enrolled at a clinic and were classified as endomorphs 28, mesomorphs 21 and ectomorphs 37 according to the system of Sheldon ("The Varieties of Human Physique", Harper, New York, 1940). Heights and weights were recorded, dietary data for a week were collected by the mothers and medical examinations were made. The range of ages was 6 to 14 years and the food intake of each child was expressed as a percentage of the National Research Council's allowances recommended for the particular age.

For energy intake the mean percentages with their standard deviations were: endomorphs, stocky or obese, 87.6 ± 24.9 ; mesomorphs, muscular, 99.8 ± 18.7 and ectomorphs, "skinny", 103.5 ± 18.8 .

Weaknesses that might have invalidated the results are considered, but the finding that the relation of the observed energy intake to body build is opposite to that expected is so definite that it cannot be ignored. For weight reduction an endomorph may require an energy intake so low as to endanger the supplies of specific nutrients in the diet.—D. Harvey.

GREULICH, W. W., CRISMON, C. S. and TURNER, M. L. (with GREULICH, M. L. and OKUMOTO, Y.) **The physical growth and development of children who survived the atomic bombing of Hiroshima or Nagasaki.** *J. Pediat.*, 1953, 43, 121-145. [Dept. Anat., Stanford Univ. Sch. Med., Calif.]

Under the auspices of the Atomic Bomb Casualty Commission, children who had been in Hiroshima and Nagasaki at the time of the atomic bombing, and most of whom had a history of epilation and radiation illness, were weighed and measured and their skeletal ages were assessed by X-ray photography in 1947 or 1948 and again in 1949 or 1950, or both, and were compared with children from Kure and children who were in Nagasaki in 1948 and 1950 but not at the time of the bombing.

The exposed and control groups were matched for ages (from 7 to 13 in 1947) and most groups contained between 100 and 200 boys or girls. The results were also evaluated relative to standard tables for Japanese children based on data collected in the SCAP Nutrition Survey of 1946-47. The findings are presented in tables and graphs.

No significant difference in height or weight was found between children exposed in Nagasaki and Nagasaki controls. In 1947 Hiroshima boys were significantly shorter and lighter than Kure boys and in 1949 significantly shorter but not significantly lighter; no significant difference was found for the girls. All groups were significantly below the standards in weight, and many, including the exposed boys, were so in height. In skeletal age exposed Nagasaki children were retarded compared with Nagasaki controls and Hiroshima children compared with Kure children, the differences being significant for boys but not for girls. It is concluded that growth and development were adversely affected by exposure to atomic bombing and some of the effects were still evident 5 years later in spite of great improvement of the food supply and general economic conditions in the interval.—W. M. Deans.

VENGE, O. **Studies of the maternal influence on the growth in rabbits.** *Acta Agric. scand.*, 1953, 3, 243-291. [Inst. Animal Breeding, Royal Agric. Coll. Sweden, Upsala.]

The rabbits used were of a small breed, the Polish, and two large breeds, the Blue Vienna and Flemish Giant, and reciprocal crosses between small and large breeds. Fertilised ova of pure

breeds and crosses were also transplanted from small to large mothers and *vice versa*.

The larger litters and the larger young, when nursed by small mothers, were undernourished during the first 3 weeks after birth. When they began to eat solid food the growth rate increased, but they were unable to catch up with the better nourished young in the next month. In cross-breeds and transplanted young the size of the nursing mother had more influence on growth than had litter size, but in purebred groups litter size was important, at least until weaning at 42 days.

In all groups except one a heavy birthweight was found to be correlated with a heavy weight at 56 days regardless of litter size; in purebred large rabbits litter size exerted more influence than with the others. Genetic constitution and maternal influence were considered to operate together on this relationship. In all groups stimulation of growth accompanied the supplementation of suckling by solid food, and the curves flattened out after weaning.

Maternal influence was strongest at first, but later the genetic growth potentialities controlled the size attained. There was no evidence of persistent maternal influence, either cytoplasmic or environmental. Genetic differences were most strongly manifested when nutrition was good.

NAKAJIMA, T. and SUGITA, T. [On the influence of the feed upon bones. 8. Effect of rice- and wheat-bran, and soya bean cake upon bones.] *Bull. Nat. Inst. Agric. Sci., Chiba* [G], 1953, No. 6, 29-35. In Japanese: English summary.

For the two previous parts see Abst. 3332, Vol. 23.

8. Adult rabbits on a diet of rice- and wheat-bran developed osteomalacia accompanied by rickets. The addition of soya bean cake to the diet improved the condition of the bone, but the rickets persisted. It is concluded that the nutrients of soya bean cake are insufficient to complete the proliferative zone of the epiphysis.

BERLIN, N. I., GOETSCH, C., HYDE, G. M. and PARSONS, R. J. **The blood volume in pregnancy as determined by P³² labeled red blood cells.** *Surg. Gynecol. Obstet.*, 1953, 97, 173-176. [Donner Lab. Med. Phys., Univ. California, Berkeley.]

Blood volume was measured by the ³²P method of Berlin *et al.* (*Amer. J. Med.*, 1950, 9, 747) once in each of 157 normal pregnant women and 34 women *post partum*, all of whom were receiving Fe by mouth. The results are tabulated and shown

N.A. and R., January 1954

graphically in comparison with values for non-pregnant women (Abst. 2025, Vol. 21).

Total red cell volume was at a low level in the second month of pregnancy and rose to a peak about 270 ml. above non-pregnant values in the ninth month; it fell again during the last month and at delivery, and 6 weeks later was still 140 ml. below normal. Plasma volume rose steadily to a peak about 1200 ml. above non-pregnant levels in the ninth month and then fell before and immediately after delivery, but was still 100 ml. above normal 6 weeks later. Total blood volume fell during the first 2 months and then followed the rise and fall in plasma volume; at delivery there was a drop of 1100 ml. to about the normal value.

These results indicate that there is true anaemia during the first 6 months of pregnancy. Whether it is due to a decrease in the rate of formation of red cells, or a decrease in their life span, or both, is not yet known.—W. M. Deans.

920

TATUM, H. J. **Blood volume variation during labor and early puerperium.** *Amer. J. Obstet. Gynecol.*, 1953, **66**, 26–35. [Dept. Obstet. Gynaecol., Sch. Med., Louisiana State Univ., New Orleans.]

Serial plasma volume estimations were made by the T 1824 method in 45 negro patients during the final stages of labour and the early hours of the puerperium. In most a transient rise, average 2.67 ml. plasma per lb. bodyweight, occurred about the time of delivery of the placenta. Since the haematocrit did not change, this presumably represented a temporary increase of circulating whole blood of the order of 900 ml. No similar change was observed in 8 caesarean deliveries under local anaesthesia. Within about 2 hr. after delivery in both series, plasma volume decreased by about 3.7 ml. per lb. bodyweight, again without change in the haematocrit. The reason for these apparent changes is obscure.—A. M. Thomson.

ROMBAUTS, P., BOURDEL, G. and JACQUOT, R. **Les facultés anabolisantes des femelles gestantes.** [**Anabolic powers of pregnant females.**] *C.R. Acad. Sci.*, 1953, **236**, 2543–2545.

Female rats received to appetite a diet containing casein supplemented with cystine 22, sucrose 25, starch 26, mixed fats 20, minerals 4, cellulose 2 and complete vitamin mixture 1 per cent. After a month they were mated; they were killed one day before the expected date of parturition. The uterus and contents were weighed and analysed for N, Ca and P. Three non-pregnant controls were similarly fed and the N, Ca and P balances of all animals were estimated throughout the experiment. The controls maintained their weight and the pregnant animals gained about 41 per cent. or, without the uterus and its contents, 20 per cent. of their initial weight. The average N, Ca and P retentions of the pregnant animals, after deducting the amounts present in uterus and contents, were 1740, 558 and 347 mg., compared with 1110, 340 and 230 for the controls.—W. Godden.

925

CURTISS, C. **Effects of a low protein intake on the pregnant rat.** *Metabolism*, 1953, **2**, 344–353. [Ziskind Res. Labs., New England Centre Hosp., Boston, Mass.]

Diets high or low in protein with different fat and NaCl contents were given to female rats after mating. Animals were killed on the 22nd day of gestation or 24 hr. after delivery. Serum protein was estimated before death. Fat content and weight of liver were estimated and the number of foetuses was recorded. Diets contained casein 20, 5 or 3, fat 38 or 5, U.S.P. salt mixture 4, NaCl 0, 2 or 4, sugar to 100 and supplements of vitamins A, D, E, B₁ and B₆, riboflavin and pantothenic acid. Choline chloride was added to a high- or low-protein diet low in fat and high in NaCl. Animals given high-fat diets were restricted to 10 g. food daily, others to 15 g. There was no significant difference in energy intake between

high- and low-protein groups. Addition of choline to a low-protein diet decreased food consumption.

In rats given low-protein diets there was a high incidence of uncompleted pregnancies associated with loss of weight during the first 2 weeks. At term rats given low-protein diets were thin and showed low serum protein and underdevelopment of mammary glands. Fat, choline and NaCl intakes did not affect fertility. Addition of NaCl to low-protein diets further reduced serum protein and there was a high incidence of oedema in the 3rd week. Fatty liver occurred in both high- and low-protein groups. Addition of choline prevented the occurrence of fatty liver and caused a rise of serum protein and reduction of oedema in rats on low-protein, high-salt diets.

The results are discussed in relation to pregnancy toxæmia in women.—F. C. Aitken.

SAARINEN, P. Lehmän veriplasman eräiden lipoidiaineosien vaikutuksesta maitorasvan muodostukseen. [Effect of some lipid components of blood plasma in the cow on production of milk fat.] *Acta agral. fenn.*, 1944, **57**, No. 2, 1-131. German summary.

This is a detailed report of 4 experiments in which 337 samples of blood or milk were taken from 54 cows for analysis. Consecutive milkings were at 4- or 6-hr. intervals during a 24-hr. period and blood samples were taken from the coccygeal artery and the udder vein half way between milkings, which were by hand. The cows were fed twice daily. The lipids were obtained from oxalated plasma samples by extraction with ether and light petroleum under regulated conditions as detailed. The components of the lipid fraction showed considerable variation in samples from the same cow over relatively short intervals, depending on the time of day and the feeding. Excessive feeding with foods rich in fat produced an increase in the lipid fraction and in its components, particularly cholesterol, in the blood plasma. Under such conditions fatty acids were present of much higher molecular weight, which seldom occurred in the milk fat.

A comparison of the hourly milk secretion and milk fat yield, as calculated from a 6-hr. period, with the lipid content of the blood plasma obtained midway between successive milkings showed that there was a positive correlation between them, and especially between the cholesterol fatty acid esters and the amount of milk and

fat produced. On the basis of results for the 4 experiments the correlation with the quantity of milk fat was $r = +0.544 \pm 0.038$ and with the yield of milk $r = +0.627 \pm 0.033$. There were variations in these coefficients from experiment to experiment, owing partly to experimental conditions and partly to defects in the analytical methods. A correction could be made if only such fatty acids in the plasma as occur in normal milk fat were included in calculating the coefficients.—W. Godden.

SENESCENCE

928

SAXTON, J. A. (JR.), SPERLING, G. A., BARNES, L. L. and McCAY, C. M. Pathologic studies of rats fed different amounts of fluid throughout life. *J. Gerontol.*, 1953, **8**, 255-263. [Lab. Animal Nutrit., Cornell Univ., Ithaca, N.Y.]

The experimental procedure was described by McCay *et al.* (Abst. 2640, Vol. 22). Pathological studies were made on 230 of the rats used in the experiments there discussed, and microscopic examination was possible in 166.

Chronic pneumonia with bronchiectasis was the most important cause of death in all groups, irrespective of age or diet. Middle-ear disease increased in frequency with advancing age, and was least common when the beverage was coffee. Chronic nephrosis was more frequent and severe on high-protein diets, had its lowest incidence on the all-milk diet and was commoner in males than in females in all groups, and its incidence increased with age. Calcium deposits in the kidneys occurred in 66 per cent. of females and 21 per cent. of males and were most frequent on the milk diet and thus were not related to nephrosis. Tumours of all types occurred in about equal numbers in males and females and increased in frequency with age. The only dietary effect was a low incidence of pulmonary lymphosarcoma in females on milk diet. Stomach ulcers occurred in 13 rats, and 5 of these had pituitary tumours. Hair-balls were found in 26 of 58 rats on milk diet and in no other group, and may have been associated with a craving for bulk with the liquid diet. All the groups were conspicuously free of vascular disease in old age compared with human beings.

The results suggest that more drastic modifications of diet than those used would be necessary to alter significantly the average life span or the pattern of ageing. Minor modifications in the pattern might be produced. The significance of the findings is discussed in relation to human senescence.—D. Duncan.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

929

ANDREONI, O. Contributo allo studio della flora batterica intestinale del neonato. [**Bacterial flora in the intestine of the newborn.**] *Boll. Ist. sieroterap. milan.*, 1953, **32**, 235-238. [Ist. Igiene, Univ. Milan.] English summary.

Meconium or faeces from 70 healthy infants aged from a few min. to 10 days was investigated during the winter for the presence of the family *Enterobacteriaceae* and of the genus *Staphylococcus*. Up to 18 hr. after birth, material from all of 29 infants was sterile except for one culture of *Staphylococcus* in the 4th hr., one of *Bacterium coli* in the 10th hr. and one of *Proteus mirabilis* in the 11th. From the 18th hr. *Bact. coli* var. *neapolitanum* became increasingly frequent, with other organisms. No sterile specimen was obtained from any infant older than one day. In all, 38 strains of enterobacteria and 12 of staphylococci were isolated.—E. M. Hume.

930

MCCARTHY, E. F. and MCDUGALL, E. I. **Absorption of immune globulin by the young lamb after ingestion of colostrum.** *Biochem. J.*, 1953, **55**, 177-182. [Lister Inst., London.]

Some Cheviot, Blackface and halfbred lambs ran with their dams, others received colostrum from their dams or other ewes after delays of from 12 hr. to 9 days after birth, during which cow's milk was given. A few lambs got no colostrum. The ewes were immunised with *Salmonella typhosa* antigen, beginning 21 days before the expected lambing date. The ewe's serum and colostrum and the lamb's serum were examined at different dates after birth, the N fraction being estimated by salt precipitation and the antibody titre being estimated. The lamb's serum was also examined by electrophoresis, and qualitative tests for protein and globulin as well as antibody titre tests were applied at intervals to urine samples.

There was an increase in serum globulin, largely due to one electrophoretic component, and an appearance of antibody in lamb serum when colostrum was given up to 29 hr. but not at 48 hr. or more after birth. After the ingestion of colostrum lambs showed marked proteinuria characterised by the presence of globulin and antibody. The results for colostrum taken from 2 ewes 3 or 12 days before birth of the lamb suggest that antibodies may be secreted in the colostrum over a relatively short period immediately before lambing.

934

GUTIERREZ, J. **Numbers and characteristics of lactate utilizing organisms in the rumen of cattle.** *J. Bacteriol.*, 1953, **66**, 123-128. [Dept. Bacteriol., State Coll. Washington, Pullman.]

Twenty-four strains of propionic acid bacteria were isolated from the rumen contents of normal dairy cows or cows with a fistula. Volatile acids were produced from lactate and in 5 strains tested the acids were found to be acetic and propionic. Seven strains isolated from silage or hays had fermentation characteristics similar to those of strains isolated from the rumen. Five strains of rumen organisms were found to grow on media incorporating infusions made from timothy hay and cottonseed meal. Four strains were isolated from soil.

These observations show that propionic acid bacteria are widely spread and it is suggested on account of the number present in the rumen, average 1.3×10^9 per ml., that they play an active part in the production of acetic and propionic acids. The rumen organisms, however, grew best under anaerobic conditions and oxygen inhibited growth to the extent that a stab culture exposed to the air showed only very slight surface growth. [It is not clear in the text whether the hay and soil strains grew under aerobic conditions, but] owing to the large numbers found on hay the possibility of their active phase being on hay rather than in the rumen is suggested.—A. T. Phillipson.

935

ANDERSSON, P. **Aureomycinets inverkan på våmfloran hos mindre idisslare. [Effect of aureomycin on the rumen flora of small ruminants.]** *Nord. Vet.-Med.*, 1953, **5**, 636-652. [Vet. Högsk., Stockholm.] English and German summaries.

Literature is reviewed. In experiments, described in detail, on 2 goats and 2 sheep aureomycin by mouth in less than therapeutic amounts caused an abrupt failure of appetite, which was restored only by omission of the antibiotic and transfer of rumen contents from a healthy animal. Rumen micro-organisms are extremely sensitive and digestion stops. One of the sheep, not given normal rumen contents soon enough, died. Some accommodation occurs when still smaller amounts are given. When aureomycin is used for therapeutic purposes, rumen contents must be given at short intervals.—I. Leitch.

936

CHANCE, C. M., SMITH, C. K., HUFFMAN, C. F. and DUNCAN, C. W. **Antibiotics in rumen digestion and synthesis. 3. The effect of aureomycin on rumen microorganisms, with special reference to the streptococci and coliform groups.** *J. Dairy Sci.*, 1953, **36**, 743-751. [Dairy Dept., Michigan Agric. Exp. Stat., E. Lansing.]

Two steers with rumen fistula were compared when feeding on a ration of 4 lb. maize and 15 lb. alfalfa-brome hay with or without aureomycin added at the rate of 0.5 or 1.0 g. daily. The pH of the rumen contents was lower when no aureomycin was given; streptococci, counted by serial dilution using dextrose azide broth, were reduced in number when aureomycin was given, but coliform organisms, counted by serial dilution using lauryl sulphate tryptose broth, increased in one animal. The differences were irregular and small. Total counts in the rumen rose significantly with increasing aureomycin intake. Total bacterial count of the faeces fluctuated considerably, but little difference was seen in the streptococcus or coliform count.—A. T. Phillipson.

937

FRANCOIS, A. C., LEROY, A. M. and ZELTER, S. Z. **Antibiotiques et phénomènes digestifs chez le ruminant. [Antibiotics and digestive phenomena in the ruminant.]** *C.R. Acad. Sci.*, 1953, **236**, 2547-2549.

The effect of aureomycin and other antibiotics on rumen fermentation was tested *in vitro*: 250 ml. rumen liquor was added to 29 g. alfalfa hay in 200 ml. buffer solution and incubated at 39° C. for 48 hr. under anaerobic conditions. The losses of cellulose and other carbohydrates yielding reducing substances on hydrolysis were estimated, and the quantity of short-chain fatty acid formed.

Aureomycin, 0.25 to 2 mg., reduced fermentation of cellulose and, to a less extent, other hydrolysable carbohydrates, but the results varied considerably. Penicillin salts produced little change, except that the procaine salt stimulated

cellulose fermentation. Chloramphenicol, dihydro-mycin and bacitracin had no effect, and streptomycin depressed fermentation.—A. T. Phillipson.

SCALETI, J. V., KULP, W. L. and CLEVERDON, R. C. **Effect of terramycin on fecal microflora of rats. 2. Therapeutic level of terramycin.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 599-602. [Dept. Bacteriol., Univ. Connecticut, Storrs.]

Balanced basal, high-protein low-carbohydrate and high-carbohydrate low-protein rations were given to groups of albino rats, with or without terramycin at the rate of 666 mg. per kg. diet.

Terramycin reduced the total aerobic and anaerobic bacterial counts in the faeces, irrespective of the ration; lactobacilli were also reduced in numbers. *Bacterium coli* and *Proteus* spp. increased in numbers and so, to a less extent, did streptococci. The only variation induced by the rations was that streptococci were fewer in the high-protein ration than in the other two.

LEIN, J., PUGLISI, T. A. and LEIN, P. S. **Unsaturated fatty acid metabolism in *Neurospora*.** *Arch. Biochem. Biophys.*, 1953, **45**, 434-442. [Dept. Zool., Syracuse Univ., N.Y.]

N.A. and R., January 1954

Mutant strains of *Neurospora crassa* were isolated which grew only in media containing unsaturated fatty acids. Four strains grew in media containing oleic, linoleic or linolenic acid, the fifth responded only to linolenic acid. None of the mutants grew in media containing acetic, butyric, caproic, capric, lauric, myristic, palmitic or stearic acid, nor did they respond to arachidonic acid.

It is suggested that the unsaturated fatty acids are synthesised by a metabolic route distinct from that of saturated acids and that they are synthesised in the order oleic → linoleic → linolenic. It is noteworthy that arachidonic acid did not support growth in *Neurospora*, although it relieves signs of unsaturated essential fatty acid deficiency in mammals.—G. A. Garton.

944

McCoy, T. A. and WENDER, S. H. **Some factors affecting the nutritional requirements of *Streptococcus faecalis*.** *J. Bacteriol.*, 1953, **65**, 660–665. [Lab. Res. Div., Samuel Roberts Noble Found., Inc., Ardmore, Okla.]

The stock of culture of *Streptococcus faecalis*, strain ATCC 6057, was maintained by 2 transfers weekly on a medium containing, per cent., glucose 1.0, yeast extract 1.0, peptone 0.8 and agar 1.5. Growth rate was estimated turbidimetrically. A suitable basal medium was developed from which individual amino-acids could be omitted.

The amino-acids essential for this organism were arginine, glutamic acid, glycine, histidine, isoleucine, leucine, lysine, methionine, threonine, tryptophan and valine. Alanine, cystine and

phenylalanine were stimulatory, and aspartic acid, asparagine, hydroxyproline, norleucine, norvaline, proline and tyrosine apparently not essential. Serine might be essential or stimulatory; studies suggested that autoclaving might produce serine from cystine.—D. Duncan.

945

HORN, M. J., BLUM, A. E., GERSDORFF, C. E. F. and WARREN, H. W. **Sources of error in microbiological determinations of amino acids in acid hydrolysates. 1. Effect of humin on amino acid values.** *J. Biol. Chem.*, 1953, **203**, 907–913. [Bur. Human Nutrit. Home Econ., U.S. Dept. Agric., Washington, D.C.]

An active material that increased the growth of *Leuconostoc mesenteroides* and *Streptococcus faecalis* in amino-acid estimation was found in acid hydrolysates of cereals and legumes prepared by several standard procedures, but not in hydrolysates of pure proteins. The material could be removed by filtering the hydrolysate at pH 4 through fritted glass, or by treating the test substance with acid and evaporating to dryness before hydrolysis.

The effect was most marked when arginine, isoleucine, lysine or valine was limiting, growth being increased by about a third; it was not noticeable when leucine or possibly threonine was limiting; intermediate effects were noted with histidine, methionine and phenylalanine. High concentrations of pyridoxamine accentuated the effect when lysine or phenylalanine was limiting.

CHENG, E., STORY, C. D., PAYNE, L. C., YODER, L. and BURROUGHS, W. **Detection of estrogenic substances in alfalfa and clover hays fed to fattening lambs.** *J. Animal Sci.*, 1953, **12**, 507–514. [Iowa Agric. Exp. Stat., Ames.]

In experiments with lambs given clover or alfalfa hay (Culbertson *et al.*, *Iowa Exp. Stat. A.H. Leaflet* No. 181, 1952) no stimulation of growth was observed, a finding which prompted the present study. The clover hay was a mixture of red, alsike and ladino, with the first predominating. Purified extracts were injected into immature female mice. The oestrogenic activities of 1 lb.

clover and alfalfa hay were each equivalent to 0.9 μ g. stilboestrol, but the potency increased to 1.95 for second-cut clover and 2.72 μ g. for third-cut alfalfa. Other feeds tested and found to have no activity were bluegrass, bromegrass, ladino clover, wheat plant, soya bean meal, yellow maize and wheat grain.—D. Harvey.

950

CHENG, E., STORY, C. D., YODER, L., HALE, W. H. and BURROUGHS, W. **Estrogenic activity of isoflavone derivatives extracted and prepared from soybean oil meal.** *Science*, 1953, **118**, 164-165. [Iowa Agric. Exp. Stat., Ames.]

Genistin, 5:4'-dihydroxy-7-glucosidoisoflavone, was isolated from solvent-extracted soya bean meal. Genistein, 5:7:4'-trihydroxyisoflavone, was prepared by hydrolysis of genistin. Immature female mice in 11 groups of 6 were used: one group, untreated, acted as control; 2 groups received injections of 0.02 or 0.04 μ g. stilboestrol, and the other groups were given genistin or genistein by mouth in doses of 2.5 or 5.0 mg., or subcutaneous injections of 1 or 2 mg. The treatments were given once daily for 4 days, the mice were killed 24 hr. after the last dose and their uteri were removed, fixed and weighed.

Both test substances by mouth in both doses increased uterine weights. Injections of genistein at both levels and of genistin at the 2 mg. level had a similar effect, and the responses were similar to those produced by injections of stilboestrol at both levels used. On this basis it was estimated that genistein had an oestrogenic activity approximately 1/50,000 that of stilboestrol. Genistin activity was rather less on a weight basis, but was equal on a molecular basis.

BELL, J. M. and WILLIAMS, K. **Growth depressing factors in rapeseed oilmeal.** *Canad. J. Agric. Sci.*, 1953, **33**, 201-209. [Dept. Animal Husb., Univ. Saskatchewan, Saskatoon.]

The growth of mice was studied on diets containing 27, 18, or 9 per cent. or no rapeseed meal, replacing linseed meal as a source of protein, or 22 per cent. water-extracted rapeseed meal. As sub-treatments 0.1 per cent. iodinated casein, 0.1 per cent. thiouracil and 50 μ g. vitamin B₁₂ per kg. feed were added singly or together. At the highest level of rapeseed meal growth was depressed. Only males responded to all the changes in level of rapeseed meal when iodinated casein was included, and at high levels the latter seemed to accentuate the growth-depressing effect. Water-extracted rapeseed meal did not depress growth. Thiouracil depressed growth on the water-extracted rapeseed and linseed meal diets, but this was counteracted by iodinated casein.

There was no definite response to vitamin B₁₂. It was concluded that up to 18 per cent. rapeseed meal may be included in the ration without causing depression of growth.

In the second experiment responses to levels of thiouracil from 0.01 to 0.32 per cent. were studied; there was no significant difference between sexes.

Flavouring agents added to rations with up to 51 per cent. rapeseed meal were studied in the third experiment. No advantage was obtained by the addition. Animal-protein factor improved growth rate on both linseed and rapeseed meals, so it was not thought to counteract directly the growth-depressing substance in the latter.

The nature of the growth-depressing substance is discussed.—T. D. Bell.

952

TRIA, E. and BARNABEI, O. **An unidentified growth-factor for yeast and hyperthyroid rats.** *Nature*, 1953, **172**, 203-204. [Inst. Gen. Physiol., Univ. Ferrara.]

When dried liver is treated with acetone, the extract evaporated to dryness and the residue treated with water, the extract obtained stimulates the growth of yeast.

In rats given a diet of soya flour, sugar, vegetable oil and salt mixture supplemented with 0.25 per cent. thyroid powder and a mixture of vitamin B₁, vitamin B₆, nicotinamide, inositol, *p*-amino-benzoic acid and folic acid there was a growth response to the extract. Hyperthyroid rats given vitamin B₁₂ responded also.

Properties of the extract are described which indicate that the active principle is not vitamin B₁₂ nor is it related to streptogenin, thioctic acid or the substance reported by Dietrich, Monson and Elvehjem (Abst. 418, Vol. 23).—F. C. Aitken.

TAUCHI, H., HAYASHI, K. and SEKIYA, M. **Experimental studies in the rabbit of changes in the weight of the liver, in the volume and number of liver cells with progress of starvation and recovery from it.** *Nagoya Med. J.*, 1953, **1**, 95-104. [Dept. Pathol., Med. Sch., Nagoya City Univ.]

About 100 rabbits were used; some were allowed to starve to death without food or water and others were given food after a period of starvation lasting from 15 to 20 days. The results of the measurements are given in a series of curves for time of starvation or recovery.

The rates of loss of bodyweight during starvation and of gain after re-feeding were greatest in the early days of the regime. During starvation loss of liver weight was relatively greater than loss of bodyweight and was greater in summer than in winter.

During starvation cell atrophy appeared earlier and was greater than nucleus atrophy and was relatively greater than the loss of weight of liver. It was also greater in summer than in winter and more marked in the centre than in the periphery of the lobule. During recovery, changes in cell volume occurred before and were relatively greater than changes in liver weight. The increase in volume was such that hypertrophy occurred, and this may have compensated for the decrease found in the number of cells at this time.

GREENWOOD, D. A., HARRIS, L. E., BIDDULPH, C., BATEMAN, G. Q., BINNS, W., MINER, M. L., HARRIS, J. R., MANGELSON, F. and MADSEN, L. L. **Feeding rats tissues from lambs and butterfat from cows that consumed DDT-dusted alfalfa hay.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 458-460. [Utah Agric. Exp. Stat., Logan.]

The tissues of lambs and the butterfat from cows which had been fed for 113 to 120 days on alfalfa dusted with DDT at a rate of up to 4 lb. per acre were given to rats for 12 to 16 weeks. Other rats were given the tissues of lambs which had received DDT in capsules at a rate of up to 200 p.p.m. hay. The concentration of DDT in the diet of the rats ranged from 0.1 to 30 p.p.m. on a dry basis. There was no significant difference in food intake or rate of growth of the rats on the highest and lowest concentrations and no sign of poisoning or change in liver or kidney. High

concentrations of DDT in the diet gave greatest storage in the body fat.—J. S. Thomson.

957

WYNN, W., HALDI, J., SHAW, J. H. and SOGNAES, R. F. **Difference in the caries-producing effects of two purified diets containing the same amount of sugar.** *J. Nutrition*, 1953, **50**, 267-274. [Dept. Physiol., Sch. Dent., Emory Univ., Ga.]

For further study of the difference in incidence of caries between Wistar and Long Evans strains of rats (Abst. 2665, Vol. 22) 2 experiments were made with the diets in use at Harvard and Emory. Both were high-sucrose diets with 64 per cent. sucrose, but they differed in details which affected their fat, protein, mineral and vitamin contents. In the first experiment rats of Wistar strain and in the second cotton rats were used. In the second experiment littermates formed a control group on a commercial stock diet.

Microscopic examinations showed an incidence of caries in both kinds of rats which was much greater with the Harvard than with the Emory diet. In the cotton rats the incidence was much lower with stock diet than with either of the purified diets.—D. Harvey.

958

MCCLURE, F. J. and FOLK, J. E. **Skim milk powders and experimental rat caries.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 21-26. [Nat. Inst. Dent. Res., Bethesda, Md.]

The incidence of caries was studied in rats of Sprague Dawley and Holtzman strains with 9 diets containing different milk powders at the 35 per cent. level, glucose 18, maize starch 45 and dried liver 2 per cent. Rats were fed to appetite from weaning until death or 90 days of age. The incidence of caries was highest with 2 milk powders prepared by commercial roller-processing, and was similar when one of these powders was given with 63 per cent. glucose and no maize starch. When 3 commercial powders were subjected to heat treatment in the laboratory their cariogenic effects were consistently increased. Most of the caries was in lower teeth and on buccal surfaces.

967

AGRELL, I. **The aerobic and anaerobic utilization of metabolic energy during insect metamorphosis.** *Acta physiol. scand.*, 1953, **28**, 306-335. [Dept. Zoophysiol., Univ. Lund.]

The changes in chemical composition during pupal metamorphosis were studied in the blowfly *Calliphora erythrocephala*.

Total N remains constant and amino-acid content is low and constant, which suggests that protein breakdown during histolysis does not proceed as far as amino-acids.

More than 95 per cent. of the total energy metabolism during metamorphosis derives from fat. Fat breakdown increases as metamorphosis progresses. A small amount of carbohydrate is also utilised. There is probably interconversion between fat and carbohydrate. During anaerobiosis no fatty acids are utilised, but glycogen decomposition is greatly increased, with formation of lactic acid and reducing sugar. More than 99 per cent. of the normal energy metabolism is blocked.

N.A. and R., January 1954

Oxygen consumption normally follows a U-shaped curve during metamorphosis and is directly related to tissue breakdown and formation. There is a corresponding decomposition and re-formation of oxidative enzymes.

Growth is complete some time before emergence, but metabolic activity continues to increase. This may be related to incorporation of soluble protein into the cellular structure, e.g., fixation of enzymes in the mitochondria; this is the period of differentiation. Different enzyme systems characterise the stages of metamorphosis. During histolysis the glycolytic system decreases and the tricarboxylic acid cycle increases in activity. During histogenesis this is reversed and during differentiation it is again reversed. There is little change in activity of the proteolytic enzymes measured at constant pH, but there is a decrease in pH during histolysis and an increase in the later stages which suffices to activate and then inactivate protein breakdown. The effects of anaerobiosis on the enzyme systems were studied. The phosphorus compounds were also studied and the results are fully discussed.—D. Duncan.

968

JODREY, L. H. **Studies on shell formation. 3. Measurement of calcium deposition in shell and calcium turnover in mantle tissue using the mantle-shell preparation and Ca^{45} .** *Biol. Bull.*, 1953, **104**, 398–407. [Dept. Zool., Duke Univ., Durham, N.C.]

A mantle-shell preparation from the oyster was used to study the formation of shell, using Ca^{45} . At least part of the Ca present in shell was taken directly from sea water by the mantle and did not enter the digestive and circulatory systems of the

organism. Most of the Ca in the mantle was inert, but that which was active had a rapid turnover.

A study of the feeding of premature infants showed that human milk alone is not the best food for rapid growth. The milk should always be supplemented with substances rich in protein and salts. Excellent results were obtained by the addition of 1 per cent. of a mixture of amino-acids, and it was shown by chromatography that administration of these acids produces a rapid rise in their concentration in the blood.

979

SEELEMAN, K. and WATERSTRADT, K. Untersuchungen über Eiweisszusätze in der Ernährung der Frühgeborenen unter besonderer Berücksichtigung der Serumproteine. [Researches on adding protein to the diet of premature infants, with special reference to the serum proteins.] *Monatsschr. Kinderheilk.*, 1953, **101**, 219-222. [Kinderklin., Univ. Hamburg, Eppendorf.]

The effect on weight, on Hb value and on susceptibility to infections and digestive disturbances of giving Plasmon, a mixture of casein and calcium, or Nutramid, a protein hydrolysate fortified with essential amino-acids, was studied with 60 premature infants. The preparations were given to alternate subjects in addition to boiled human milk with added ascorbic acid, but no significant difference in response could be detected between the groups. Electrophoretic fractionation of the serum proteins of 30 of the infants when between 7 and 35 days old showed no significant difference between the groups in the amounts of total protein, albumin, globulin and γ -globulin. There was thus no evidence that casein or cow's milk was less satisfactory for premature infants than special mixtures of essential amino-acids.

HANSEN, J. D. L. and SMITH, C. A. Effects of withholding fluid in the immediate postnatal period. *Pediatrics*, 1953, **12**, 99-113. [Boston Lying-in Hosp., Mass.] Spanish summary.

Nine infants who received no water for the first 3 days of life were compared with 9 who were given moderate amounts. The average weight loss during this time was 13 per cent. when water was withheld and 8 per cent. when it was given. The daily output of Na, K, Cl and N in the urine was unaffected by water intake. Infants of less than 36 weeks' gestational age excreted relatively larger amounts of electrolytes than mature infants. In 7 other babies who received glucose and water, the loss of weight was much less, indicating conservation of body water, but the expected Na-sparing and protein-sparing effects were not demonstrated. It is concluded that omission of water for 3 days after birth is permissible, but that if fluid is given it should be as glucose solution.

STEWART, A. and WESTROPP, C. Breast-feeding in the Oxford Child Health Survey. 2. Comparison of bottle- and breast-fed babies. *Brit. Med. J.*, 1953, **ii**, 305-308. [Social Med. Unit, Univ. Oxford.]

For Part 1 see Abst. 3400, Vol. 23.

Of the 580 babies studied, 142 were breast fed for less than 1 month, 84 were weaned from the breast in the second or third month, 119 in the fourth or fifth, and 235 were breast fed for 5 months or more. At the end of 12 months the first group were heavier than the last and had more teeth. There was no systematic difference between groups in skeletal maturity or patency of fontanelle. The percentages of babies crawling at 10 months and walking at 14 months were least in the last group. The overall infection rates of gastro-enteritis, bronchitis and otitis media between 2 and 12 months were not related to the duration of breast feeding. Gastro-enteritis was rare when babies were receiving breast milk only, reached a maximum at weaning, and was especially common among babies who began to be

N.A. and R., January 1954

weaned in the sixth month. Head colds were almost equally common in breast- and bottle-fed babies.—F. C. Aitken.

GYLLENSWÄRD, C. **Breast-fed children compared to artificially fed children in a series from a Children's Home.** *Acta Soc. Med. upsalien.*, 1953, **58**, 285-311. [Paediat. Clin., Kronprinsessan Lovisas Barnsjukhus, Stockholm.]

The 142 children studied mostly entered the home at or before 2 weeks of age and stayed until 8 months; some stayed longer. Forty-nine were entirely or almost wholly breast fed for at least 6 months, 18 were entirely breast fed for 3 months and 75, most of whose mothers did not accompany them to the home, were almost entirely artificially fed. These groups were otherwise comparable. The children wholly or mainly breast fed gained weight better than the artificially fed throughout the period of observation, which extended beyond the introduction, as late as possible, of supplementary feeding. There was no difference between groups in the incidence of infections.—F. C. Aitken.

985

SIMPSON, A. S. **Breast versus artificial feeding: influence on weight gain.** *Med. Officer*, 1953, **90**, 85-87. [Ashton-under-Lyne, Lancs.]

The weight gains of 1382 infants born in a health division of Lancashire County Council during the year 1950 and the first half of 1951 were considered in relation to the duration of breast feeding.

Infants who were not breast fed or who received breast milk for less than 2 months were 9 to 10 oz. heavier at the end of the first year than those who were breast fed for longer than 2 months. Differences between the groups other than diet did not appear to be of importance in this study.

DROESE, W. and STOLLEY, H. **Vergleichende Untersuchungen über die Aufzucht von Säuglingen mit Kondensmilch und mit den bisher üblichen Milchemischungen. Zugleich ein Beitrag zur Frage des Kohlenhydratbedarfs der Säuglinge in der Klinik. [Comparison of infants reared on condensed milk and on the usual milk mixtures. The question of the carbohydrate requirement of infants in hospital.]** *Monatsschr. Kinderheilk.*, 1953, **101**, 285-292. [Kinderklin., Univ. Kiel.]

One hundred and eighty-eight infants, aged from 14 days to 10 months, recovering from acute or chronic nutritional disturbances, were fed on whole milk mixtures or unsweetened evaporated milk mixtures. The evaporated milk was tolerated as well as the usual whole milk mixtures,

except in the first 3 months of life, and altering the nature of the curd by adjusting the temperatures of homogenisation and sterilisation did not increase the digestibility of the evaporated milk. In all age groups susceptibility to fresh infections was significantly less in infants having evaporated milk mixtures. The question of there being special carbohydrate requirements with evaporated milk was studied, but the supplements necessary were similar to those for the usual milk mixtures. Requirement varied with the individual infant.

TEZNER, O. **Nahrungseiweiss und Reststickstoff. [Diet protein and residual nitrogen.]** *Ann. paediat.*, 1953, **181**, 177-183. [Mothercraft Training Centre "Wizo", Tel Aviv.] English and French summaries.

Ten infants, of whom 9 were aged between 3 weeks and 2 months, 3 were premature, 1 mongoloid, 1 dystrophic and the others healthy, were given in successive weeks a half-milk diet based on dried milk of stated composition and supplying from 2.8 to 4.9 g. protein per kg. bodyweight daily, and a diet based on dried buttermilk, supplying from 5.2 to 11.1 g. protein per kg. bodyweight daily.

Some gained more on the second diet than on the first, others the reverse. After a week on the high-protein diet blood residual N was considerably raised in all but 1, and in 2 reached abnormally high values, 44 and 45 mg. per cent. One of these developed signs of toxicosis, e.g. loss of weight, pallor, apathy and loss of turgor, but recovered in a few days when treated with tea diet and then put on half-milk diet. All the others thrived on the buttermilk diet. Nevertheless, care in the use of high-protein diets is recommended lest toxicosis result. A brief discussion of the concept of toxicosis is appended.—W. M. Deans.

A review.

989

DEAN, R. F. A. **Plant proteins in child feeding.** *Med. Res. Counc. Spec. Rep. Ser.* No. 279, 1953, pp. viii + 163. H.M.S.O., London. Price 10s. net.

This report is in 2 parts. The first, in 49 pages, reviews the relevant literature on composition of breast milk, amino-acid requirements of children, evaluation of dietary proteins, need for milk

substitutes with an account of substitutes which have been used, and tests with laboratory animals and man of the value of supplementing plant proteins.

The second part describes in full feeding trials made during a study of undernutrition in Germany in 1946 to 1949. A short preliminary report has already been published (Abst. 819, Vol. 20). Cereal and soya bean mixtures with or without dried skimmed milk were compared with cow's milk as supplement to the diets of children in 2 orphanages and 2 schools. Cereal, soya bean and milk mixtures were tested also as substitutes for part of the cow's milk in the diet of young babies. Twenty-five newborn children, 25 aged from 6 to 12 months, 50 from 1 to 2 years, 50 from 2 to 6 years and 625 from 7 to 11 years took part in the trials, in which 3 combinations of barley, wheat and soya flours without milk, 4 with dried skimmed milk and 2 of barley, maize and soya flour with dried skimmed milk were tested for periods of between 8 and 24 weeks. Trypsin inhibitor was destroyed wholly or partly in all but one mixture. In the orphanages tests were conducted with comparable groups of children receiving the same basic diet, but the diets of the schoolchildren could not be controlled. The benefits of the supplements were assessed in terms of the ratio of actual to standard weight gain for each child. Two of the mixtures were discarded because they produced digestive upsets.

Faults in the manufacture of the mixtures and illness unconnected with the diets caused difficulties in interpreting the results. The most successful trial was with children between 1 and 2 years of age who grew well and who were in good clinical condition when given a cereal-soya mixture without milk for 16 weeks. The proportion of energy intake supplied by the mixture was between 40 and 50 per cent. Inclusion of 12½ per cent. dried skimmed milk conferred no additional benefit, but 25 per cent. caused greater progress. A supplement of cereal-soya mixture equivalent in energy to 500 g. fresh milk for children of 2 to 5 years and to 750 g. milk for children of 7 to 11 years gave good gains, but mixtures with 10 per cent. dried skimmed milk gave slightly better results. The results of removing trypsin inhibitor were inconclusive but seemed slightly favourable. Replacement of wheat by maize caused no obvious alteration in quality, and such a mixture with 10 per cent. dried skimmed milk was successfully given to newborn infants to supply 40 to 50 per cent. of total energy. The amino-acid content of the different mixtures was studied, but it did not account for differences in the effectiveness of different mixtures.

A special study was made of the energy intakes of children aged from 40 to 125 weeks and a rela-

tion was shown to exist between intake and weight for age.

Appendices to the report include some studies with trypsin inhibition *in vitro* and rat growth studies; the latter showed the benefit of adding dried skimmed milk to cereal-soya mixtures, the marked increase in growth rate produced by giving vitamin B₁₂ to rats on a cereal-soya ration and the benefit of removing trypsin inhibitor, which was nullified by bad manufacture of the mixture.—F. C. Aitken.

LAL, S. B. **The effect of pressed ground-nut cake flour in supplementing rice diet.** *Indian J. Med. Res.*, 1952, **40**, 471–479. [Pub. Health Lab., Patna 4.]

Boys in an Indian orphanage were divided into 3 groups of 17 or 18, of mean ages of 11·0, 10·3 and 9·0 years. The control group received a rice diet with vegetables; for the other groups this was supplemented with 1 oz. daily of pressed ground-nut cake flour or skimmed milk powder. Both supplements were beneficial in increasing height, weight and Hb value, the weight increase being somewhat greater with groundnut flour than with milk. The general health of the children was also improved by both supplements.—D. Duncan.

ZIEGLER, M. R. **Mineral-enriched meats for diets of infants requiring a milk substitute.** *J. Amer. Dietetic Assoc.*, 1953, **29**, 660–665. [Dept. Paediat., Univ. Minnesota, Minneapolis.]

A summary is given of the results of previous experiments (Abst. 4856, Vol. 17; McQuarrie and Ziegler, *Pediatrics*, 1950, **5**, 210), in which young rats were found to grow as well on a meat diet, provided Ca and P were added, as on a milk diet. On the basis of this work, a mineral-enriched meat diet was devised to replace cow's milk in the

feeding of infants or children for whom milk was contraindicated because of allergy or other disorder. Strained meats were used, with veal bone ash as main source of minerals; full details of composition and preparation are given. Satisfactory N, Ca and P retentions were found in 6 patients, and 2, one an infant with milk allergy and the other an infant with high blood galactose, are described in detail.—W. M. Deans.

995

SACKETT, W. W. (Jr.) **Results of three years experience with a new concept of baby feeding.** *Southern Med. J.*, 1953, **46**, 358-362 (with discussion 363). [Dept. Med. Res., Univ. Miami, Fla.]

It is reported that satisfactory results were obtained by starting babies with 6-hourly feeds from birth and by introducing cereals at 2 to 3 days of age, strained vegetables at 10 days, strained fruits at 17 days and varying the diet at weekly intervals. The midnight feed was abandoned as soon as possible and the regime changed to 3 meals a day. For mothers able to breast feed their infants this system was, in general, no more difficult than 4-hourly feeding, and most mothers who were willing to co-operate in the new method were enthusiastic about its results. The paper gives a general account of the method; details of 300 babies reared in this way are to be given later.—A. M. Copping.

ANGELINI, B. and PENNATI, E. **Rilievi sull'accrescimento e sui problemi assistenziali del lattante distrofico. [The growth of the dystrophic infant and the problem of assistance.]** *Lattante*, 1953, **24**, 15-25. [Ist. Clin. Pediat., Univ. Milan.] English summary.

Of 1700 children treated for dystrophy in the Paediatric Clinic in 1946, 132 relapsed. Of the 132, 10 were lost sight of, and 38 died of some intercurrent complication, 23 of them within the first year of life. In 1951, therefore, 84 were

Vol. 24, No. 1

surviving under observation. They belonged mostly to a low social level and lived in poor hygienic conditions. Originally all of them were 30 per cent. or more underweight. By the age of 5 or 6 years the development of a good number of the children was within the normal limits. It is concluded that many dystrophic children are inherently capable of making a good recovery but that many come from homes in which recovery is impossible. Further public assistance, even if it involves institutional life, is considered to be the only means of betterment for such children. A central institute for rehabilitation of dystrophic children is recommended, like the Paul Parquet Centre in Paris.—E. M. Hume.

SANTYAN Y VELASCO, S. **Studio statistico e considerazioni sui sistemi di allattamento nella provincia di Modena, in base ai dati dei Consultori dell' O.N.M.I. nel quinquennio 1947-51. [Statistical study and discussion on systems of breast feeding in the province of Modena, based on information from welfare clinics of the O.N.M.I. in the five years 1947-1951.]** *Lattante*, 1953, **24**, 3-9. [Clin. Pediat., Univ. Modena.] English summary.

The number of births in the province of Modena declined steadily in the years 1947 to 1951, but the number of infants brought to the clinics of the O.N.M.I. increased. The death rate in the first year of life in the province declined from 8.64 per cent. to 5.19 per cent.; among infants attending the clinics it was fairly constant at somewhere over 2, although the percentage breast fed (entirely breast fed for at least 5 months) among the infants attending the clinics declined from 52 to 41. It is considered that propaganda in favour of breast feeding should be continued and intensified.

PARENT, M. and MASSARDO-RAYMAEKERS. **Expérience d'alimentation complémentaire faite dans une consultation de nourrissons. [Supplementary feeding at an infant welfare centre.]** *Ann. Soc. belg. Méd. trop.*, 1953, **33**, 57-66. Flemish summary.

The mean age of the infants studied was 10 months; they were underweight and showed mild signs of kwashiorkor. The mothers received rations from their employer, but through ignorance the infants were weaned on to a predominantly carbohydrate diet. A daily supplement containing 11.5 g. arachis oil, 7.5 g. sugar, 4.5 g. maize flour and 25 g. dried skimmed milk was given to all the infants, of which one group was under observation for 22 months and another for from 7 to 17 months. The mean respective weight deficiency

from Schlesinger's norms for the 2 groups was before treatment 1.925 and 2.010 lb., and at the end 1.540 and 1.405 lb. A study of the growth curves, however, showed that the mean increase of weight from birth to the beginning of supplementary feeding was about 2.0 lb. below the expected gain, but during the period of supplementary feeding the gain exceeded the expected gain by 0.385 and 0.605 lb. for the 2 groups. At the end of the study the children appeared in excellent condition, though their physical development was that of their weight, not of their age. It is suggested that supplements given earlier would have allowed normal growth.—L. Wills.

BEAL, V. A. **Nutritional intake of children. 1. Calories, carbohydrate, fat and protein.** *J. Nutrition*, 1953, **50**, 223-234. [Child Res. Council, Denver, Colo.]

The data reported are based on the evaluation of 604 diet histories obtained on 46 children during the first 5 years of life. Quartile, maximum and minimum intakes referred to age and bodyweight are tabulated and graphed along with National Research Council recommended allowances. The findings are discussed.—F. C. Aitken.

1004

SPOLVERINI, L. Nel complesso della popolazione italiana quelli che mangiano peggio sono i bambini. [**Of the whole Italian population the worst fed are the children.**] *Riv. Clin. pediat.*, 1953, **51**, 569-578.

Children between 2 and 6 years old are considered the worst fed, their diet being composed largely of food made with white flour, and a little olive oil. The mothers' diets are considered to be deficient in pregnancy, and full lactation is impossible of achievement. The author pleads at length for better bread and *pasta* by restoration of the old dark flour, rather than by fortification of highly milled white flour.—E. M. Hume.

1005

LAMBERTS, J. H. Een onderzoek naar de sociale toestand, de voedingstoestand en het intelligentiequotiënt van Rotterdamse schoolkinderen in 1947, 1949 en 1951. [**Investigation into the social class, diet and intelligence quotient of Rotterdam schoolchildren in 1947, 1949 and 1951.**] *Tijdschr. soc. Geneesk.*, 1952, **30**, 347-364. [Rotterdam.]

In 1947, there were examined 444 children aged 6 to 9 years from 356 families and 4 schools in working-class areas; in 1949, 108 children from working-class families and in 1951, 156 children from the highest, intermediate and lowest school classes.

The social survey included information on place of birth, employment, education and details of house and household equipment and management. I.Q. was estimated by the method of Terman and Merrill. Clinical data collected were height and weight, the Van der Heyden and *sacratama* indexes, presence of signs of deficiency, blood pressure and pulse rate, Hb, red cell count, and blood total protein, globulin, cholesterol, Ca, inorganic P, vitamin A, carotenoids and vitamin C.

Many correlations have been measured. For instance, children that slept alone had a significantly higher mean I.Q. than those that slept two or more in one bed. Children with better sleeping quarters were taller and heavier and had higher blood Ca than those with poor quarters. I.Q. rose as mean size of family fell and as social status improved, but there was no significant change in blood chemistry with social class. Boys of the upper classes were heavier and taller than those of the working class, but differences were less and not significant for girls. Hb was lowest in the poorer workers' children but was low in all. For further comments on measurements and clinical data see Abst. 2760, Vol. 22.

Thyroids were obviously enlarged in 12 per cent. of the children.

The general conclusion is drawn that the children of working-class families lack milk and overcompensate with fruit in their diet. They require supplementary feeding in school.

CUVELIER, B. V. J. (with VERDONK, G.) Enkele beschouwingen over de voeding van de Belgische bevolking. [**Some views on the diet of the Belgian people.**] *Voeding*, 1953, **14**, 320-337. [Biochem. Centrum, Rijks Univ., Ghent.]

N.A. and B., January 1954

The diet of the Belgian people is discussed in terms of the daily consumption per head of 14 foods, including beer and coffee, from data given by the Ministry of Economic Affairs for the years 1948 to 1951. In quantity, potatoes head the list with 400 g., beer follows with 360 and milk with 274 g. The others listed are in g.: bread 322, sugar 60, pig meat 49.5, beef 45.3, egg 33.6, butter 29, margarine 21.3, coffee 15.7, cheese 15.4, horse-flesh 9.3 and frozen beef 4.4. Beef and butter took the highest percentages of cost. Costs are outlined in detail. Quality of the diet is represented by a series of diagrams in which total intakes of 10 components are compared with requirements [standard not stated] and the amounts supplied by each "food" are shown. Only P, Fe and "Vitamine PP" are in excess of needs. Protein is about 82.5 per cent. of needs and half of it is of animal origin. Amino acid supplies are, on the average, adequate, with cystine in poorest supply.—I. Leitch.

1008

KARVONEN, M. J. La diététique des travailleurs de force. [The feeding of heavy workers.] *Gaz. méd. France*, 1953, **60**, 35–36. [Inst. Méd. Travail, Helsinki.]

The interactions of hard work and digestion are discussed and some preliminary details are given of the food habits of the champion lumberjacks of Finland in 1951. They drank milk in large quantities, as much as 2½ litres daily. For breakfast they liked porridge, 100 to 350 g., with sugar and a lot of butter, 25 to 50 g. They had a light mid-day meal and a large meal after work was over for the day. This is contrary to the Finnish tradition of 3 substantial meals a day, and it is suggested that other workers, both outdoor and indoor, might modify their habits with advantage.—W. M. Deans.

1009

DEJEAN, CARRÈRE, P., TRÉMOLIÈRES, J., POMMEAU, Y., CHABERT, DE GASQUET and BERNET. Étude sur l'alimentation et les dépenses familiales en milieu artisanal à Marseille en 1952. [Study on diet and family expenditure among tradesmen in Marseilles in 1952.] *Bull. Inst. nat. Hyg., Paris*, 1953, **8**, 449–487.

A study was made in Marseilles in the summer of 1952, by methods previously used, of representative families of tradesmen working on their own account, with or without journeymen or apprentices; some were selling goods made elsewhere, others not. The contrasting trades selected were plumbing (prosperous, 56 families with 207 persons) and shoemaking (precarious, 57 families with 186 persons). Sixty-two per cent. of the

plumbers were of French origin, but only 17 per cent. of the shoemakers.

On the whole, suitable amounts of butter, fruit and vegetables were consumed. Meat consumption was adequate but not excessive. Large quantities of cereals were used, but not very much bread; no dried vegetables. Mean energy and nutrient consumptions were satisfactory; fat and vitamin A were more than adequate. There were, however, unusually great variations between families, e.g., meat consumption ranged from 18 to 270 g. per head daily and milk from zero to over ½ litre. Plumbers' families with children had a low Ca intake and shoemakers' families with children had also a low intake of animal protein. Plumbers' families with children fared better than dockers' families (Abst. 2703, Vol. 22) or large families in general (Abst. 4918, Vol. 23).

Menus were simple. The principal meal was at mid-day; the evening meal always included soup, often other items left over from mid-day, but rarely meat. Fish dishes and fish soup (bouillabaisse) were frequent.

Daily food expenditures per head were: plumbers without children 345, with children 288; shoemakers without children 250, with children 264 fr. Food expenditure formed, respectively, 59, 55.7, 58.3, 60.1 per cent. of total expenditure. In plumbers' families 31.5 per cent. of food expenditure went on meat, fish and eggs, in shoemakers' families 27 per cent. Seventy-five per cent. of the plumbers' wives and 47 per cent. of the shoemakers' wives considered their families were adequately fed; those who did not mostly blamed lack of money. Although on the average consumption of meat was adequate (101 g. for the 2 groups taken together), 30 per cent. would have liked more; next came fruit and fish.

About 1/3 of the women in each group had work other than home duties, the plumbers' wives usually in the shop, the shoemakers' wives outside the home and business. The effect was that both groups spent more on food and the diet of the shoemakers' families was distinctly improved; that of the plumbers' families was already adequate.—W. M. Deans.

1010

DEN HARTOG, C. De voeding van de Nederlandse haringvisser op een haringdrijfnet-schip. [Diet of Netherlands herring fishers on a drifter.] *Voeding*, 1953, **14**, 337–341.

The regulations for the diet of seamen in the herring fishing industry are discussed. The amounts of foods usually provided are listed and their value in nutrients, with certain alternatives e.g., fresh or pickled vegetables, is computed. The probable composition of the diet is about: Cal.

3700, protein 100 g., fat 200 to 240 g., carbohydrate 300 to 400 g., Ca 0.84 to 1.0 g., Fe 13 to 20 mg. and vitamins, A 2400 I.U., carotene 100 to 2375 μ g., B₁ 1570 to 2260 μ g., riboflavin 1380 to 1870 μ g., nicotinic acid 10 to 18 mg. and, so long as potatoes are adequate for the trip, vitamin C about 100 mg., but temporarily as low as 3 mg. if potatoes are finished and there are only pickled vegetables.—I. Leitch.

1011

SARKAR, A. K. and SARKAR, N. **Dietary survey of a nurses' hostel in West Bengal.** *J. Indian Med. Assoc.*, 1953, **22**, 415-418. [Nurses' Hostel, Fraser Hosp., Burdwan, W. Bengal.]

The food of 165 nurses was weighed raw for one year and the average nutritive value of the diet was calculated. Intakes of nutrients fell somewhat short of the amounts which would be obtained from the diet prescribed by the authorities and fell substantially short of average requirements of nutrients, excepting Fe and nicotinic acid. The requirements were based on Indian and American recommended allowances. Suggestions are made for improvement of the diet.—F. C. Aitken.

N.A. and R., January 1954

[Inst. Invest. Med., Madrid.] English summary.

This assessment of the nutritive value of the commonest dishes in the Spanish cuisine includes the quantities of the raw ingredients used in preparing the dishes, the protein, fat and carbohydrate contents and the energy value of the cooked product, and the amounts of these in a helping of average size.—M. B. Richards.

MINISTERIO DE SANIDAD Y ASISTENCIA SOCIAL, CARACAS. Programa de nutrición para los centros de salud publica. "Plan mínimo." Manual de procedimientos. [Nutrition programme for public health centres. "Plan mínimo." Instruction manual.] *Inst. Nac. Nutric., Caracas, Venezuela*, April 1953, pp. 59.

The classification of families in 3 economic groups is described on the basis of information collected by health visitors. They are the educable, where better use of income is needed, the educable-assistance, where both types of help are required, and the assistance, where little can be done without financial aid. The second part of the manual deals with the training which the health visitor herself must undergo.

DONATH, W. F., FISCHER, I. A., VAN DER MEULEN-VAN EYSBERGEN, H. C., and DE WIJN, J. F. Voorlopige mededelingen omtrent een onderzoek naar het resultaat van voeding zonder dierlijke eiwitten. [Preliminary report on the investigation into the effect of diet without animal protein.] *Nederland. Tijdschr. Geneesk.*, 1953, **97**, 2118–2122. [Nederlands Inst. Praev. Geneesk., Leyden.] English summary.

This is a rewrite from a more clinical point of view of data already presented and described in *Abst.* 4919, Vol. 23.—I. Leitch.

1026

Lectures on prenatal care. *Nederl. Bond Moederschapszorg., The Hague*, 1953, pp. 64.

These collected lectures are published by the Netherlands Association for Maternal Care and Child Health. They were delivered to medical practitioners in Leyden and Rotterdam and first published in *Tijdschr. Soc. Geneesk.*, 1953, **31**, Nos. 11 and 12. There is a foreword by the Minister of Public Health in which he quotes from Dr. Posthuma's review of infant mortality that one out of 30 pregnancies ends prematurely and perinatal (obstetric) deaths number 4 times all deaths from tuberculosis.

The lectures are propaganda, and a basis for

Vol. 24, No. 1

improved prenatal care. The introductory statement of the problem is by de Haas, that on obstetrical care by Schmidt. Three lectures are devoted to nutrition: a general one on diet and health by Roovers, a short review of experimental studies of diet in pregnancy by den Hartog and one on feeding the family, the pregnant woman and on the family budget by Van Schaik. There is also one on social aspects of prenatal care by Remmelts, two on mental hygiene by Van der Spek and Van Kooten, and finally a review by Posthuma of perinatal mortality in the Netherlands and elsewhere from 1926 to 1950, a most useful review. Altogether, it is a clear and fair, if not critical, statement of presently accepted views that should be helpful to all occupied in the work of maternal clinics.—I. Leitch.

OLAYA R., J. La educación higienica y la nutrición escolar. [Health education and nutrition of the schoolchild.] *Bol. Ofic. sanit. panamer.*, 1953, **34**, 326–330. [Serv. Coop. Interamericano Salud Púb., Colombia.] English summary.

In Colombia the programme for health education and improvement of nutrition in schoolchildren was hampered by lack of suitable teachers at advanced levels. The plans were modified to give, to the children at school and to their parents, simple instructions on the basic principles of health and nutrition, with demonstrations of a balanced diet in the school canteen. The participation of the whole community in the financing and running of nutrition-education projects was a means of making the importance of nutrition widely appreciated. The success of a co-operative nutrition education programme combined with a school meals service in the department of Valle del Cauca is reported, and it is suggested that similar programmes could be built up in other areas.—A. M. Copping.

FOOD ECONOMICS AND STATISTICS

- 1042
SCHULZ, T. **A 'human needs' diet: April, 1953.** *Bull. Inst. Statistics Oxford*, 1953, **15**, 249-254.
The cost of a "human needs" diet for a family of 5 in April 1953 was 65s. 3d., i.e., 1s. 7½d. more than in November 1952 (Abst. 2161, Vol. 23).
In previous papers the amount of Ca supplied daily by the diet was given as 0.6 g. instead of 0.7 g. owing to an erroneous assumption about the Ca content of national bread and flour.

FERGUSON, T. and LOGAN, J. C. **Mothers employed out of the home.** *Glasgow Med. J.*, 1953, **34**, 221-244. [Dept. Pub. Health, Univ. Glasgow.]
In 1951 and early 1952 a study was made in Glasgow of 350 married women who were employed outside the home and of 350 who were not; all had infants aged about 7 months and the 2 groups were closely matched for socio-economic background, though not for size of family.

In general, work outside the home tended to have an adverse effect on reproductive performance and family health. Breast feeding was commoner and lasted longer in mothers not working outside the home. Fourteen per cent. of those in factories breast fed for at least 12 weeks; 25 per cent. of those in shops and 24 per cent. of those in domestic work, but many of both these categories were working only part time. Babies breast fed for at least 12 weeks had less illness than others. Of the school-age children of mothers in jobs, barely half were having school meals.

Over 60 per cent. of the mothers in jobs declared they had to work in order to make ends meet, and this was borne out by a study of the money available for housekeeping, including rent. Nevertheless, mothers in jobs did not spend more on food; they had more club and hire-purchase commitments, and there was evidence that fathers' contributions to housekeeping money were

less where mothers were earning, though whether this was cause or effect was not clear.

The social implications are discussed.

W. M. Deans.

1044

CLARK, C. **Population growth and living standards.** *Internat. Labour Rev.*, 1953, 68, 99-117.

Many Malthusians disclaim anti-religious preconceptions and claim to be purely scientific in outlook. "If that is so, there cannot be any other group of scientists so ill informed on the facts with which they are supposed to deal. Many Malthusians have no knowledge of the simplest facts about population; and those who do know some demography seem to be almost universally uninformed on economics."

The law of increasing returns which commonly applies in industry, i.e., where increase of output results in increasing returns per unit of labour or other economic resources employed, is little known and less regarded in discussions of population and resources. Very few areas of the world are overpopulated in relation to resources. In agriculture, with Denmark as standard, enormous increases in population and production are possible. "The world's total area of cultivable land (allowing for double cropping in the highest rainfall tropical areas) is 24 million square miles, and at Danish standards of cultivation and consumption could support 12,000 million people, as opposed to the 2300 million people it supports now."

The fertility of the human race is usually overestimated and the effect on it of apparently small changes, such as deferment of marriage by only a year or two, as has been happening in India, is not appreciated. The rise in production in India since 1870 has been far greater than the rise in population (often regarded as one of the major problems) and there is every prospect that it will so continue.

Speed of development depends on capital accumulation, and extension of agricultural production often requires capital investment comparable with that in developing manufacturing industries. The conditions necessary to growing prosperity are: for the few isolated overcrowded areas, freedom to emigrate; open markets for the goods from poor but expanding countries, and capital help for those least well endowed.

SCHRADER, F. M. and WOOLLAM, G. E. **Seasonal variation in prices and production of livestock and livestock products.** *Canada Dept. Agric., Marketing Serv., Econ. Div., Ottawa*, April 1953, pp. 2, 33 Charts.

The livestock and products dealt with include beef animals, certain beef cuts, pigs, pork and bacon, veal, lamb, milk, butter, eggs and chickens.

Vol. 24, No. 1

Twenty charts and one table based on data referring to the period from 1933 to 1950, but excluding the war years when prices were controlled, show the seasonal variations in prices and production. Where trends were found 13 additional charts were prepared showing the changes in these during the period 1921 to 1950.—D. Harvey.

1046

WOOLLAM, G. E. **The influence of prices on the relative consumption of beef and pork.** *Canada Dept. Agric., Marketing Serv., Econ. Div., Ottawa*, June 1953, pp. 9.

On the assumption that wholesale prices reflect consumer demand, the annual domestic consumption of beef and pork in Canada and the prices of these on the Toronto market were analysed for the period 1927 to 1950. It was apparent that when the price of beef was high relative to that of pork, the consumption of beef was relatively low. About 90 per cent. of the variation in consumption of beef expressed as a percentage of consumption of pork was associated with variation in the price of beef expressed as a percentage of the price of pork. The average relation between relative prices and consumption during the period was such that a 1 per cent. change in the price of beef relative to that of pork resulted in a 1 per cent. change in the opposite direction in the consumption of beef relative to that of pork.

A technical appendix gives details of the statistical methods used.—D. Harvey.

1047

BANNA, A., ARMORE, S. J. and FOOTE, R. J. **Peanuts and their uses for food.** *U.S. Dept. Agric. Marketing Res. Rep. No. 16*, 1952, pp. 99. [Bur. Agric. Econ., Washington, D.C.]

About a third of this report consists of statistics on groundnuts (peanuts) in the U.S. for the last 30 or 40 years: production, prices, marketing regulations, imports, exports and uses in the home market. The fluctuations and trends are discussed in detail with the aid of further tables and 6 graphs.

Five of the southern states produce most of the crop, Georgia leading with 34 per cent. Production has risen steadily since 1909 and rapidly during the two world wars to a record of 2336 million lb. picked and threshed in 1948, with a slight subsequent decline. In addition, some are cut as hay or used as pasture for pigs. Imports almost disappeared after 1929 and have been forbidden since 1943. Exports were considerable during the immediate post-war years but are now small.

Domestic consumption has increased with production. For the years 1937-41 the total average

domestic consumption was 944 million lb. on a kernel basis, divided as follows: edible uses 609, crushing for oil 203, seed 114, feed for livestock 18 million lb. In 1950-51 consumption per head in edible uses was about 4.4 lb. (kernel basis), compared with 6.5 lb. in 1945-46, when competing foods were scarce and money plentiful, and 2.4 lb. in 1909-13. Peanuts roasted in shell now account for only 8 per cent. of the total edible use; consumption in this form is greater among the lower-income groups and in the South. Expenditure on shelled peanuts rises sharply with income, that on peanut butter less sharply. Of the shelled

peanuts about half are used to make peanut butter, the other half being about equally divided between candy and salted peanuts. Popcorn is believed to be a major competitor of salted peanuts. Peanut butter has to compete with jam, cheese and other sandwich fillings, for which prices are also quoted.—W. M. Deans.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

1049

GOVIL, K. K. Clinical assessment of nutritional status of school boys in Uttar Pradesh. *Indian Med. Gaz.*, 1952, 87, 567-573. [Provincial Hyg. Inst., Lucknow.]

The methods prescribed by the Indian Council of Medical Research (1948) were used for examining 6371 boys, of whom 90 per cent. were from rural and 10 per cent. from urban districts. Ages ranged from 5 to 16 years and from measurements of weight, height and intercrystal diameter, mean values for which are given, growth was shown to be greatest between 13 and 15 years. Classification of physique by appearance resulted in 3.7, 55.7, 37.2 and 3.3 per cent. being described as good, fair, poor and very poor, respectively. Of the total number 59.3 per cent. were affected by one or more of the deficiency conditions, and the percentages of them in the groups ranged from 28.8 in the good to 82.1 in the very poor.

The incidence of deficiency signs is tabulated in detail. Those of vitamin A were common and those of other vitamins less frequent, the incidence increasing, as expected, in the groups with the poorer physique. Of the boys 81.7 per cent. had no dental caries.—D. Harvey.

1050

SQUIRES, B. T. Tongue patterns of African children in health and in malnutrition. *Trans. Roy. Soc. Trop. Med. Hyg.*, 1953, 47, 329-333. [Med. Serv., Bechuanaland Protectorate.]

Permanent records of tongue patterns were prepared by DiPalma's method with an ink prepared from T 1824 dye (*Arch. Int. Med.*, 1946, 78, 405). Counts made of filiform and fungiform papillae in unit areas of the tongues of 400 apparently healthy children showed a ratio 4.5:1. Similar prints were prepared also for another group of 458 children. For 402 of them clinical exam-

ination showed no malnutrition and 381, 95 per cent. of these, had normal tongues. Of 56 in whom malnutrition was noted, 54 had abnormal tongues. Disappearance of filiform papillae caused the ratio of these to fungiform papillae to fall to 2:1 or less.

Such tongue prints are considered to be useful as permanent records of nutritional disease.

D. Harvey.

1051

SQUIRES, B. T. The ultra-violet fluorescence of the tongue in African children. *S. African Med. J.*, 1953, 27, 759-760. [Med. Serv., Bechuanaland Protectorate.]

Fluorescence was absent from a much higher proportion, 51 and 40 per cent., respectively, of the 873 African and 44 European children examined than that of 11 per cent. reported by Tomaszewski (*Brit. Med. J.*, 1951, i, 117) for his subjects under 20 years of age. Hagerman and Hirschfield (*Acta dermato-venereol.*, 1947, 27, 369) have shown that fluorescence increased in certain subjects given vitamin B complex, but the changes noted in 87 of these Tswana children when they returned to a poorer diet after a period of better feeding were not significant. A smaller group of 38 African children with well marked signs of malnutrition did show no or only faint fluorescence.

A general review.

1055

AMIES, C. R., LOEWENTHAL, L. J. A., MURRAY, N. L. and SCOTT, J. G. **Blindness in the Bantu. A survey of external eye disease and malnutrition in the North Eastern Transvaal.** *S. African Med. J.*, 1953, 27, 593-597. [S. African Inst. Med. Res., Johannesburg.]

People numbering 259 and 253, belonging to the Bavenda and Shangaan tribes of north-eastern Transvaal, were examined for eye diseases and signs of malnutrition. The incidence of trachoma among Shangaan was more than 7 times that among Bavenda, 48 and 6.5 per cent., a result attributed to the more insanitary conditions and greater number of flies found among the Shangaan. In this and an earlier survey (Amies *et al.*, *S. African Med. J.*, 1952, 26, 362) blindness from leucoma was common. Assessment was made of the nutritional state of the population from the number of occurrences of 8 signs, mainly in the skin, which were considered to have nutritional significance. The index for these, *i.e.*, the frequency per head of population for all signs together, was greater for the Bavenda, 0.69, than for the Shangaan, 0.53.

The evidence makes untenable the view that the high incidence of blindness among Bantu is due largely to malnutrition.—D. Harvey.

1056

MANSON-BAHR, P. **The causation of tropical sprue. A hypothesis.** *Lancet*, 1953, 265, 389-391. [Hosp. Trop. Dis., London.]

It is suggested that tropical sprue is primarily a virus infection of the intestinal tract and secondarily a nutritional disturbance due to changes in intestinal flora and interference with absorption.

F. C. Aitken.

1057

SCHORNAGEL, H. E. **The connection between nutrition and mortality from coronary sclerosis during and after World War II.** *Doc. Med. geograph. trop.*, 1953, 5, 173-183. [Lab. Pathol. Anat., Municip. Hosps., Rotterdam.]

An analysis of the post-mortem findings for the period 1940 to 1950 showed a marked drop in mortality from coronary sclerosis and thrombosis

during the war and a rapid increase to pre-war levels immediately after it. The number of thromboses increased absolutely and relatively from 1945 to 1950. From these findings and from a study of the literature it is concluded that the increase in mortality after the war was due to the increased intake of fat and the more liberal nature of the diet, and that severe restriction of food, particularly of lipids, might have a favourable influence on the incidence of cardiac infarction.

L. Wills.

1058

HIGGINSON, J., GERRITSEN, T. and WALKER, A. R. P. **Siderosis in the Bantu of Southern Africa.** *Amer. J. Pathol.*, 1953, 29, 779-815. [Baragwanath Non-European Hosp.]

Tissues from 44 post-mortem examinations were examined microscopically and the Fe content was estimated in selected organs from 21 of them. The findings at 252 other examinations were reviewed and the livers from these were sectioned and stained for Fe; 110 biopsy specimens of liver were also examined. Liver blocks from 72 Bantu in other territories were available for comparison. Detailed descriptions of macroscopical and microscopical appearances are given. Two cases of haemochromatosis in Europeans were similarly investigated.

Siderosis in the Bantu both from its frequency of occurrence and from its distribution in the liver and reticulo-endothelial system is considered to differ fundamentally from haemochromatosis, in which the Fe storage is believed to be mainly parenchymal. The ingestion of abnormally large amounts of Fe (see Abst. 4125, Vol. 20) as possible cause is suggested for further investigation.

DEFICIENCY DISEASES

General

1060

JELLIFFE, D. B. and ONWUMERE, R. E. **Malarial chemoprophylaxis and weight gain in West African infants.** *J. Trop. Med. Hyg.*, 1953, 56, 187-189. [Dept. Med., Univ. Coll., Ibadan, Nigeria.]

A small-scale trial with 26 Yoruba infants aged from 7 to 10 months and treated for a time with proguanil suggested that malaria is not the main cause of poor growth in African infants. More extended studies are called for.—W. M. Deans.

1061

FRIEDMAN, A. **Experiences in two hundred eighty-nine cases of infantile diarrhea in a nutritionally deficient group of infants.** *Amer. J. Dis. Child.*, 1953, **85**, 675-687. [Dept. Paediat., Rambam Govt. Hosp., Haifa, Israel.]

The children studied were mostly those of new immigrants into Israel in 1950 and 1951, 85 per cent. of whom had come from Moslem countries. Only those under 2 years of age and suffering from diarrhoea with severe dehydration were considered. Examinations of specimens of blood and stools were made in addition to clinical examinations. In the protozoa and bacteria isolated, pathogenicity was confirmed only for *Shigella* and *Salmonella* infections. Of the 289 children 53 per cent. had parenteral infection, the commonest being acute pharyngitis and bronchopneumonia. Nearly all were underweight, half suffered from frank malnutrition, 40 per cent. were anaemic and 30 per cent. rachitic. Frequency diagrams are given for values of serum albumin and globulin, Hb and red cell counts and Ca, P and acid phosphatase in serum.

Intravenous therapy only was given for 8 to 12 hr., after which oral feeds of buttermilk, half milk, skimmed or protein milk were also given. Buttermilk gave the best results. Sulphonamide preparations were the principal antibacterial substances used.

The highest incidence was in the 4th month of life and in spite of hospital treatment 58 of the children died. The relatively low incidence among younger babies is attributed to the serious attempts at breast feeding made by nearly all mothers of Middle Eastern origin.—M. S. Fraser.

1062

BANSI, H. W. **Somatische Spät- und Dauer-schädigungen nach Dystrophie. [Late and permanent body damage from dystrophy.]** *Deutsch. med. Wochenschr.*, 1953, **78**, 1318-1321. [I. Med. Abt., Allg. Krankenhaus St. Georg., Hamburg.]

In this lecture delivered to a psychiatrists' society, the question of disabilities in ex-prisoners-of-war which may be the late results of starvation are discussed. These are considered under the headings of heart and circulation, gastro-intestinal tract, liver, skeletal system and complicating infections, e.g., tuberculosis. Many symptoms and complaints must be regarded as of psychic origin, and not the direct result of dystrophy. The liver, being the organ most endangered by dystrophy, must be taken into account as a possible seat of late injury. Osteoporosis may gradually develop from loss of Ca due to the diarrhoea frequent in hunger oedema. The manifestations of tuberculosis during imprisonment and also the later

appearance of a new infection may be considered to be results of starvation. An unsatisfactory aspect is that of the great number of subjective disorders among returned prisoners.

M. B. Richards.

1063

MOGILNICKI, R. **The advanced malnutrition of forced labour camps.** *J. Trop. Med. Hyg.*, 1953, **56**, 159-162.

Incarceration in the hospital of a forced-labour camp north of the Arctic Circle in the U.S.S.R. in 1940-41 gave the author the opportunity to examine several thousands of prisoners.

Work was heavy and for at least 14 hr. daily. The diet consisted of black rye bread, dry salted fish, barley groats and tea, with occasional supplements of vegetables or meat. The patients were pale and haggard, with no visible muscle configuration or subcutaneous fat. The legs and other parts of the body were swollen, and the nails were brittle. During the short summer months, the faces, necks and backs of the hands showed a dry, scaly, pigmented eczema, and other parts also of the body were pigmented especially round suppurating sores. The state of the tongue varied from smooth and scarlet to grey and deeply furrowed with vivid red edges. The lips and corners of the mouth were sore and encrusted or peeling, and the gums pyorrhoeic. There was extreme anaemia with a weak pulse and low blood pressure. There was little fluid in the body cavities. The muscles showed degenerative reactions with few reflexes. The stools were frequent, watery and black, with some blood. Protein deficiency and pellagra predominated in the general state of malnutrition.

Treatment was primitive, but when permitted by the authorities, all but the worst cases responded to a diet of raw minced beef with or without injections of nicotinic acid. Relapse was rapid, and death frequent on return to work.

At autopsy the brain was hyperaemic, with much fluid in the subarachnoid spaces. The skeletal muscles were pale and all the fatty tissues behind the sternum and round the kidneys were gelatinous, hydropic and transparently grained. The pericardium and pleura were smooth, the heart enlarged and flaccid and the lungs hypostatic. The thymus gland could not be found and the thyroid was small. The liver and spleen were small, crumbly and watery. Both the liver and the kidneys were devoid of pattern. The adrenal glands were small, with no medulla and a thin structureless cortex. The stomach and intestinal walls were thin and of a grey colour; in a few cases only, there was penetration of dysenteric ulcers of the bacillary type.

The author had the opportunity to confirm that a similar condition prevailed in other oppressed

nations of the Soviet Union, insidious, long-standing starvation, particularly of protein, being associated with excessive physical strain.

GOPALAN, C., VENKATACHALAM, P. S. and SRIKANTIA, S. G. **Body composition in nutritional edema.** *Metabolism*, 1953, **2**, 335-343. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

The patients studied were male adults in advanced stages of chronic starvation. The body composition was estimated on admission to hospital, and in some cases immediately after the disappearance of clinical oedema. In the oedematous stage the absolute plasma volume values were decidedly low; there was a large increase in extracellular fluid, and an increase in total body water, and the cellular solids constituted an abnormally small proportion of the bodyweight. After treatment there was a reduction in extracellular fluid both absolutely and relative to bodyweight, a reduction in total body water, and an absolute increase in cellular solids. The clinical grade of oedema was found to be roughly proportional to the product of the amounts of body solids per kg., extracellular fluid per kg. and intracellular fluid per kg. bodyweight. In nutritional oedema there was evidence not only of excessive extracellular but also of excessive intracellular hydration.—M. B. Richards.

1066

TORRES UMAÑA, C. Estudio sobre edema distrofico. [Study of dystrophic oedema.] *Rev. española Pediat.*, 1953, **9**, No. 50 Extraord., 279-286. [Univ. Nac. Colombia, Bogotá.] French, English and German summaries.

In infants suffering from dystrophic oedema, caused chiefly by lack of animal protein, hypochromic anaemia and leucopenia were common. An increase in the volume of the liver, with fatty degeneration, was also frequently found. In some cases purpura due to thrombopenia was observed.

M. B. Richards.

1067

BLANKHART, D. M. **Nutrition and hepatic diseases on the Island of Sangir.** *Doc. Med. geograph. trop.*, 1953, **5**, 7-24. [Mission Hosp. Taruna, Sangir, Indonesia.]

Immediately after the war, during which the intake of protein had decreased, the incidence of cirrhosis of the liver and other signs of nutritional

deficiency had increased over the pre-war level. Post-mortem examination of 17 selected patients of all ages showed marked steatosis in 3 infants, steatosis with cellular infiltration and fibrosis in 4 infants and young children, and cirrhosis in 10 patients aged from 5 to 32 years. The findings are considered to support the view that if a protein deficiency persists cirrhosis may develop in a fatty liver and that a high incidence of cirrhosis in a population suggests protein deficiency.—L. Wills.

1068

KERPEL-FRONIUS, E. and VARGA, F. **The problem of oedema in infantile malnutrition.** *Acta paediat.*, 1953, **42**, 256-264. [Dept. Paediat., Univ. Pécs, Hungary.] French, German and Spanish summaries.

In 380 severely wasted infants, oedema was found in only 8, 2 per cent. The reasons for its rarity were investigated. In most, the recognised oedema-promoting conditions were absent. In spite of low energy intake, extreme deficiency of dietary protein was rare. Dehydration often counteracted the tendency to oedema. It is concluded that oedema is common only in certain types of infantile malnutrition which occur in war time or in tropical countries and that then it is associated with low blood protein.—M. S. Fraser.

1069

JANSSEN, E. **Some aspects of kwashiorkor.** *Doc. Med. geograph. trop.*, 1953, **5**, 128-136. [Dept. Paediat., Gen. Hosp., Pretoria, S. Africa.]

A short general article deals with the literature and the author's own investigations. It is concluded that kwashiorkor is a disease of childhood, that it is produced by faulty diet and not by an infection, though infection is often the cause of death, and that isolation of the patient as a protection against infection is imperative. Arrest of growth is considered the central and most important sign; if the arrest is not treated the full syndrome develops. The long-term problem of prevention is discussed.—L. Wills.

1070

ARENDS, A. and NIEWEG, H. O. **Schadelijke gevolgen van eiwitarme voeding. [Harmful effects of low-protein diet.]** *Nederland. Tijdschr. Geneesk.*, 1953, **97**, 2123-2129. [Lab. Pathol. Anat., Rijks Univ., Groningen.] English summary.

Low-protein diets in the treatment of disease may be dangerous. Five cases are described. In the first 2, low-protein diet was prescribed for kidney disorders and continued in one for 1½ years and in the other for 6 years, after which time there was also disturbance of liver function. Both patients had macrocytic anaemia, successfully

treated by intramuscular injection of 15 μ g. vitamin B₁₂ daily. The third patient had nephritis, for which he ate a low-protein diet for a year, and "erythroblastic" anaemia. At post-mortem examination advanced atrophy of the spleen was found, in the etiology of which deficiency of vitamin B₁₂ or other member of that group may have been involved. The fourth developed necrosis of the liver in association with a half-year's low-protein diet for hypertension, and the fifth, prescribed a diet without meat, fish or egg for asthma, died with diarrhoea and steatorrhoea and with post-mortem findings of fatty liver and atrophy of the intestinal mucosa.—I. Leitch.

HIPSLEY, E. H. Dietary "fibre" and pregnancy toxæmia. *Brit. Med. J.*, 1953, ii, 420-422. [Australian Inst. Anat., Commonwealth Dept. Health, Canberra.]

Published observations on the incidence of toxæmia or eclampsia in population groups with different dietary habits or exposed to changes in diet are briefly reviewed, and the diets are assessed in terms of fibre content. The term fibre includes lignin, cellulose and hemicelluloses. It is concluded that toxæmia is more common where the fibre content of the diet is low and the suggestion is made that some component associated with the fibre of the diet tends to prevent the occurrence of toxæmia.—F. C. Aitken.

1075

WELLEN, I. The infant mortality in specific hypertensive disease of pregnancy and in essential hypertension. *Amer. J. Obstet. Gynecol.*, 1953, **66**, 36-45. [Dept. Obstet. Gynaecol., Coll. Med., Univ. New York.]

Infant mortality, defined as the combined still-birth and neonatal death rates, was studied among

27,028 hospital and private patients delivered during a 15-year period; 5.17 per cent. of the pregnancies were complicated by hypertensive disease, which was mainly specific hypertensive disease of pregnancy, i.e., pre-eclampsia and eclampsia, or essential hypertension, or a combination of these. Infant mortality was 2½ times normal in severe cases of the specific disease and 3 times normal when that was present as a complication of essential hypertension. In these conditions, the losses were particularly high when calculated on the basis of intrauterine deaths not explained on other grounds, e.g. foetal deformity or birth injury. The incidence and consequences of certain other features of these hypertensive cases is described, especially the nature of the delivery, and prematurity.

Vitamin A

1077

BHATTIA, I. S. Studies on vitamin 'A' deficiency. *Bull. Central Food Technol. Res. Inst. Mysore*, 1953, **2**, 204-207. [Central Food Technol. Res. Inst., Mysore.]

Dark adaptation was measured with a biophotometer in 63 adults and 37 children at Lahore in the Punjab during 1945. The adults included 20 members of the university staff and 16 research workers. Measurements were made before and after exposure to a bright light. Forty-seven per cent. of those examined had normal dark adaptation, 39 per cent. were subnormal and 14 per cent. doubtful. Abnormality was more pronounced in the children, which was attributed to the relatively greater requirement of vitamin A during growth. Abnormality was more prevalent among the less well paid, only 45 per cent. of the university menial staff having normal capacity for dark adaptation, but 61 per cent. from a higher income group.—I. M. Sharman.

ORBANEJA, J. G., VIVANCO, F., PALACIOS, J., BUYLLA, A. and QUIÑONES, P. Vitamina A

N.A. and R., January 1954

y afecciones dermatológicas. [Vitamin A and skin disease.] *Rev. clín. española*, 1953, 50, 124-129. [Clin. Dermatol., Hosp. San Juan De Dios, Madrid.] English, German and French summaries.

Vitamin A and carotene were estimated photo-colorimetrically in blood serum of 54 patients with skin diseases. In 40 per cent. the values were below 80 I.U. per 100 ml. and in 53 per cent. above 130. Improvement in the skin condition did not appear to be related to the vitamin content of the serum. The results are discussed with particular reference to the findings of Leitner and Moore (Abst. 1212, Vol. 18).—A. M. Copping.

SNYDERMAN, S. E., MORALES, S., CHUNG, A. W., LEWIS, J. M., MESSINA, A. and HOLT, L. E. (Jr.) Absorption of fat and vitamin A in premature infants. 3. Effect of surface active agents on the absorption of these substances. *Pediatrics*, 1953, 12, 158-164. [Dept. Paediat., Coll. Med., Univ. New York.] Spanish summary.

Healthy premature infants between 4 and 38 days of age were given a standard milk preparation of dried cow's milk and cane sugar designed to provide 130 Cal. per kg. bodyweight, 15 per cent. of the calories being from protein, 35 from fat and 50 from carbohydrate. Complete collections of faeces were made by use of metabolism frames or plastic diapers for periods of 4 days. The first period was usually arranged as a control, in the second a surface-active agent was given, and the third was again a control. In the first test 9 infants were given a supplement of Tween 80, 40 mg. per g. fat, which increased the average fat absorption from 71.8 per cent. to 81.1 per cent. and vitamin A absorption from 60.3 per cent. to 73.0 per cent. In the control period after the test fat absorption fell again only to 77.9 per cent. and vitamin A absorption to 63.4 per cent. To test the possibility that the unpalatability of Tween 80 might have had an unfavourable effect a further test with Tween G1205 was made with 11 other infants. The average percentage fat absorption then rose from 60.9 to 74.9, and the vitamin A absorption from 58.5 to 74.0. In neither series was improved absorption seen in every individual. A few other tests are reported with maize oil instead of butterfat in which absorption of fat was improved and there was then less benefit when Tween was added. Some

measure of improvement was found in an older child with biliary atresia who showed a rise in fat absorption from 46.6 to 54.3 per cent. on addition of Tween. A child with cystic fibrosis of the pancreas showed no improvement.—I. M. Sharman.

1081

KATSAMPES, C. P., MCCOORD, A. B., HAMBURGER, R. N. and CLAUSEN, S. W. Absorption of vitamin A aldehyde by children. *Pediatrics*, 1953, 12, 191-197. [Dept. Paediat., Sch. Med. Dent., Univ. Rochester, N.Y.] Spanish summary.

Single doses of vitamin A alcohol, aldehyde or acetate in concentrated solution in Wesson oil were given orally to human volunteers or patients, mostly infants and children, at the rate of 7000 I.U. per kg. bodyweight. Absorption was assessed by estimating the level of vitamin in the blood 4½ and sometimes 7 hr. later. In 5 normal children, ranging in age from newborn to 12 years, vitamin A aldehyde was efficiently converted to vitamin A. The increase in the vitamin A value of the plasma was about the same after giving vitamin A aldehyde as after giving equivalent amounts of vitamin A alcohol to the same subjects. In 5 patients with fibrocystic disease of the pancreas the value for vitamin A in the plasma was little changed after treatment with vitamin A acetate, but the increase after treatment with vitamin A alcohol or aldehyde was almost as great as in normal subjects. In 6 patients with coeliac disease the increase was much below normal with all three forms of vitamin A. Absorption of vitamin A aldehyde was examined also in 31 patients with various diseases. In 7, including cases of infestation with giardia and oxyuris, the maximum value reached in the blood plasma was from 0 to 361 I.U. per 100 ml., and absorption was considered to be poor. In 10 other patients the maximum value was from 160 to 847 I.U. per 100 ml., and in the remainder from 1102 to 4951; absorption was classed as intermediate and good, respectively.—T. Moore.

1082

DATTA, P. K. and RAJAGOPAL, K. Studies on metabolism of vitamin A. 1. Vitamin A and urine. *Indian J. Med. Res.*, 1952, 40, 487-494. [Sect. Biochem., All-India Inst. Hyg. Pub. Health, Calcutta 12.]

Specimens of urine from patients with pulmonary tuberculosis, acute nephritis, myeloid leucaemia and lobar pneumonia were examined for vitamin A, protein, uric acid and purine bodies. Of 21 samples from tubercular patients only one contained vitamin A, 18 I.U. per 100 ml.; out of 28 cases of lobar pneumonia 16 contained detectable amounts of the vitamin. No parallel was

observed between the amount of vitamin A excreted, and the amount of protein or purines excreted or the white blood cell count. When shaken with the nonsaponifiable fraction of shark liver oil most specimens of urine took up measurable quantities of vitamin A into solution. Freshly voided urine from normal subjects also took up measurable amounts of vitamin A when shaken with the nonsaponifiable fraction of halibut liver oil. The effect was not observed, however, when the urine became denatured on standing for 24 hr. or when the pH was altered. Heating had a marked effect on the solvent capacity, and boiling for 10 min. under reflux completely prevented solution. Plasma protein fractions prepared according to the method of Cohn were added to specimens of urine and their effect on the solubility of vitamin A was examined. There was a slight increase with one fraction only. Addition of xanthine and hypoxanthine slightly increased the solubility of vitamin A, but adenine and guanine had no effect.

CLAROS NAVARRETE, C. Tocoferolemia en estado normal. [Blood tocopherol in healthy subjects.] *An. Fac. Farm. Bioquím., Lima*, 1951, 2, 504-515. [Lab. Bioquím. Esp., Univ. Nac. Mayor de San Marcos, Lima.]

The photocolorimetric method of Emmerie and Engel with ferric chloride was used to estimate the tocopherol content of the blood in healthy young adults, 20 men and 10 women. The values in mg. per 100 ml. serum ranged from 0.03 to 0.14 with a mean of 0.09 in the men and from 0.12 to 0.17 with a mean of 0.14 in the women. The findings are discussed with reference to reports in the literature which state that the normal values for vitamin E in human blood lie between 0.05 and

0.15 mg. per 100 ml., the amounts in plasma and serum being about the same.—A. M. Copping.

1086

Coagulazione e alfatocifero. [Coagulation and alpha tocopherol.] *Acta gerontol.*, 1953, 3, No. 2, 38-40.

A short annotation is made on the high value attributed to α -tocopherol in combating post-operational embolism.—E. M. Hume.

1087

BLATT, M. H. G., WIESBADER, H. and KUPPERMAN, H. S. Vitamin E and climacteric syndrome. Failure of effective control as measured by menopausal index. *Arch. Int. Med.*, 1953, 91, 792-799. [Dept. Obstet., Coll. Med., Univ. New York.]

Vitamin E was compared with oestrogens and other drugs as a means of controlling the climacteric syndrome. The occurrence of vasomotor symptoms, paraesthesia, insomnia, nervousness, melancholia, vertigo, fatigue, arthralgia and myalgia, headaches, palpitation and formication was observed in over 700 patients. The results were converted into menopausal indices by a system which gave more importance to some of the abnormalities, such as the vasomotor symptoms, than to others. Vitamin E, given as from 80 to 100 mg. *dl*- α -tocopheryl acetate daily, was ineffective, the symptoms being controlled in only 25.6 per cent. of patients treated with it, compared with 33 per cent. of patients given placebos. A daily dose of 0.05 mg. ethinyl oestradiol controlled the symptoms in 92.6 per cent. of patients treated, and a dose of 1.25 mg. conjugated equine oestrogenic substances in 90.8 per cent. Phenobarbital was effective in 42.8 per cent. of the patients treated.—T. Moore.

Vitamin B Complex

1088

EHRENBERG, R. and BRÖRKEN, C. Zur resorptionsfördernden Wirkung des Vitamins B₁ (Aneurin). Eine biologische Naturkonstante. [Absorption-promoting action of vitamin B₁ (aneurin). A natural biological constant.] *Naturwissenschaften*, 1953, 40, 413. [Physiol. Inst., Univ. Göttingen.]

Ten fasting subjects were given 80 g. cane sugar in 145 ml. water, alone in the first test and subsequently with 6, 8, 10, 12 or 16 mg. vitamin B₁. Blood sugar values were measured after the sugar was taken, at 10-minute intervals in the first hour and twice in the second hour. Vitamin B₁ increased the rate of absorption as indicated by the time of the maximum rise in blood sugar, and the optimum effect was obtained with 10 mg.

SCURO, L. A. Studio dell'eliminazione urinaria di acido pantotenico in corso di trattamento antibiotico. [Excretion of pantothenic acid in the urine during treatment with antibiotics.] *Acta vitaminol.*, 1953, **7**, 143-146. [Ist. Clin. Med. Gen., Univ. Rome.] French, English, German and Spanish summaries.

Free pantothenic acid was estimated microbiologically in the urine of groups of 5 subjects before and for 15 days during treatment with penicillin, aureomycin, or chloramphenicol; 5 were untreated. The amount excreted in the urine by all the groups in the 24 hr. ranged from 1.62 to 3.48 mg. It fluctuated considerably but there was no consistent progressive decrease.—E. M. Hume.

1103

GHEITA, A. Pantothenic acid in the treatment of wounds. A hope or a fact? *J. Roy. Egypt. Med. Assoc.*, 1953, **36**, 239-243. [Kasr-el-Aini Hosp., Cairo.]

An ointment containing pantothenic acid was applied to ulcers and operation wounds which had previously been very slow to heal. Complete healing of the operation wounds occurred in about

10 days and of the ulcers in 25. General treatment with tonics and antibiotics was continued while the pantothenic acid ointment was applied. It was considered that healing was accelerated by the ointment.—A. M. Copping.

1104

WACHSTEIN, M. and GUDAITIS, A. Disturbance of vitamin B₆ metabolism in pregnancy. 2. The influence of various amounts of pyridoxine hydrochloride upon the abnormal tryptophan load test in pregnant women. *J. Lab. Clin. Med.*, 1953, **42**, 98-107. [Dept. Pathol., St. Catherine's Hosp., Brooklyn, N.Y.]

See also Abst. 2238, Vol. 23.

When a test dose of 10 g. DL-tryptophan was given to 86 pregnant women at term, only 4 excreted less than 3 mg. xanthurenic acid, an amount regarded as the upper limit of normal. The administration of 5 mg. vitamin B₆, 7 mg. riboflavin and 50 mg. nicotinic acid before the test had no effect on the excretion of xanthurenic acid, but excretion was normal after administration of 25 mg. pyridoxine hydrochloride between 24 hr. before and 1 hr. after the test dose of tryptophan, or of 5 to 15 mg. 30 min. before the test. A daily dose of 10 mg. pyridoxine throughout pregnancy gave a normal excretion test at term.

L. Wills.

1105

GIRDWOOD, R. H. A folic acid excretion test in the investigation of intestinal malabsorption. *Lancet*, 1953, **265**, 53-60. [Dept. Med., Univ. Edinburgh.]

Folic acid and citrovorum factor in the urine were estimated microbiologically. The test dose was 5 mg. folic acid given orally or subcutaneously; the test subjects were saturated with folic acid before the tests if it was thought that the tissues were unsaturated. In 11 control patients with other diseases, with one exception, and in 3 healthy subjects, output of folic acid was not less after the oral than after the subcutaneous dose. In 11 patients with evidence of impaired absorption from the small intestine, including idiopathic steatorrhoea, sprue and refractory iron-deficiency anaemia, excretion after the oral dose was significantly less than after the subcutaneous dose. In some of these patients there was malabsorption of some substances such as iron and folic acid, but not of others, such as fat. In 15 patients with pernicious anaemia, some treated and some in relapse, there was no evidence that the absorption of folic acid was impaired. There was no evidence of malabsorption in 5 women with megaloblastic anaemia of pregnancy, though previously the author (Abst. 5030, Vol. 23) had obtained evidence of malabsorption in such subjects. The results

N.A. and R., January 1954

are discussed and those in the last type of case are considered to have been due to the failure sometimes of the tissues to utilise folic acid.—L. Wills.

1106

ZUMOFF, B. **Possible relationship of folic acid to uric acid metabolism as exemplified by a case of non-tropical sprue.** *Amer. J. Med. Sci.*, 1953, **225**, 674–676. [Med. Serv., Jewish Hosp., Brooklyn, N.Y.]

The blood uric acid value was high before treatment in a patient with non-tropical sprue and severe megaloblastic anaemia. On treatment with folic acid, it decreased as blood regeneration occurred. It is suggested that the increase might have resulted from an increase of the xanthine oxidase level in the tissues like that which occurs in folic-acid-deficient animals.—L. Wills.

1107

BJÖRKENHEIM, G. **Influence of folic acid on the nervous system in pernicious anemia. Experiences relating to pernicious tapeworm anemia.** *Acta med. scand.*, 1953, **145**, 406–409. [4. Med. Clin., Maria Hosp., Univ. Helsinki.]

In 75 of the 95 patients studied with pernicious tapeworm anaemia, signs and symptoms of subacute combined degeneration were present; improvement followed removal of the worm with or without administration of vitamin B₁₂. In the single subject treated with folic acid in whom nerve signs were absent, they developed after a month, during which the patient took 140 5-mg. tablets of folic acid and a small amount of liver extract, though the blood picture was normal. After withdrawal of folic acid and parenteral treatment with vitamin B₁₂ the signs improved. These findings and the literature are discussed, and it is concluded that the use of folic acid, whether with liver extract or alone, is contra-indicated in pernicious anaemia.—L. Wills.

1108

OSMOND, T. G. **Post-partum anemia: a practical treatment.** *Practitioner*, 1953, **171**, 77–80.

The Hb value of women who were anaemic after the loss of 1000 ml. or more of blood at delivery was restored to normal more rapidly when in addition to routine oral administration of iron and ascorbic acid, they were given either a single injection of crude liver extract within 24 hr. of delivery, or 6 mg. folic acid daily. The crude liver extract produced the most rapid results and the greatest subjective improvement.—L. Wills.

1109

SAWITSKY, A., MEYER, L. M., MCINERNEY, R. and DIFENBACH, W. C. L. **Oral treatment of pernicious anemia with citrovorum factor (Leu-**

covorin). *Acta med. scand.*, 1953, **145**, 332–337. [Med. Serv., Queens Gen. Hosp., Jamaica, N.Y.]

Four out of 5 patients with pernicious anaemia in relapse responded to citrovorum factor in oral doses of from 0.15 to 15 μ g. daily. An optimum response and normal blood picture were obtained with the smallest dose but the patient relapsed after 2 months' maintenance treatment with the same dose. Another patient reached and maintained a normal blood picture with 15 μ g. daily. In the other 2 patients the response was suboptimum. Leucovorin had no effect on the neurological signs.—L. Wills.

DAS GUPTA, C. R., CHATTERJEA, J. B. and BASU, P. **Vitamin B₁₂ in nutritional macrocytic anaemia.** *Brit. Med. J.*, 1953, **ii**, 645–649. [Dept. Haematol., Sch. Trop. Med., Calcutta.]

In trials with 22 patients having nutritional macrocytic anaemia, improvement was assessed by the formula of Della Vida and Dyke (Abst. 2812, Vol. 12). Vitamin B₁₂, injected in amounts ranging from 30 to 300 μ g. daily, produced initially good responses in 14 of the patients but only 5 of them showed continuous improvement; the reticulocyte response was poor and macrocytosis persisted. There was no definite correlation between the nature of the response and the size of the dose. Folic acid in amounts of from 210 to 900 mg. daily was given orally to 14 of the patients who had failed to give an optimum response to vitamin B₁₂; 6 showed a good response and in 4 of them the blood picture became normal. Finally, crude liver extract was given parenterally to 8 patients whose blood had not become normal after both vitamin B₁₂ and folic acid; all improved but only 3 became normal. Vitamin B₁₂ given orally also produced a suboptimum response which was not related to the size of the dose or the degree of gastric acidity. The results suggest that there is deficiency of both folic acid and vitamin B₁₂ in nutritional macrocytic anaemia and that the folic acid deficiency is primary.—L. Wills.

1111

KLEINSORGE. "Erfahrungen mit Vitamin B₁₂." [Experiences with vitamin B₁₂.] *Folia haematol.*, 1951–53, **71**, 420–423. [Med. Poliklin., Univ. Jena.]

Experience with vitamin B₁₂ in the treatment of pernicious anaemia and in animal experiments is reported. In rabbits rendered anaemic by injection of lead the recovery time was from 14 to 16 days compared with 4 weeks in untreated anaemic animals; red cells that showed punctate basophilia disappeared rapidly on the commencement

of treatment. In the same way, in a human case of lead poisoning, 3 injections of 15 μg . vitamin B₁₂ caused the disappearance of punctate basophilia.

SCHILLING, R. F. and DEISS, W. P. Intrinsic factor studies I. Paper electrophoresis of mixture of gastric juice and radioactive vitamin B₁₂. *Proc. Soc. Exp. Biol. Med.*, 1953, 83, 506-509. [Dept. Med., Med. Sch., Univ. Wisconsin.]

Paper electrophoresis was used to study the fixation of radio-active vitamin B₁₂ in concentrated human gastric juice. It appeared that radio-active vitamin B₁₂ was bound to a component of gastric juice which moved towards the anode and was not included in one of the major protein peaks. After the mixture of gastric juice and vitamin B₁₂ had been boiled, it was difficult to localise the vitamin in electrophoresis. In electrophoresis with serum or saline, vitamin B₁₂ showed a tendency to move towards the cathode, so that the reaction with the component of gastric juice was highly characteristic and might lead to identification of Castle's intrinsic factor.—A. M. Copping.

MOLLIN, D. L. and ROSS, G. I. M. Serum vitamin B₁₂ concentrations of patients with megaloblastic anaemia after treatment with vitamin

B₁₂, folic acid, or folinic acid. *Brit. Med. J.*, 1953, ii, 640-645. [Dept. Pathol., Postgrad. Med. Sch., London.]

Euglena gracilis var. *bacillaris* was used as test organism. Injections of from 20 to 1000 μg . crystalline vitamin B₁₂ were given to 33 patients with pernicious anaemia in relapse and repeated at different time intervals. The serum value for vitamin B₁₂ before treatment was below 100 μg . per ml., the lower limit of normal; after treatment the value rose to within the normal range, the height of the rise and its duration varying roughly with the size of the dose. When the mean serum value was 250 μg . per ml. the marrow was normoblastic but when the mean value decreased to 86 μg . per ml. the marrow became megaloblastic again. Estimation of the amount of the vitamin retained showed that the greater the retention the longer the serum value remained within normal limits. After the smaller doses, though the serum values were within the normal range, the mean was below that of normal subjects, but after the larger doses the mean value was as high as that of the normals. After daily parenteral doses of 40 or 1 μg . of the vitamin the serum value became normal in 1 and 15 days, respectively. Although the serum values were much higher after the bigger doses the differences in the haematological responses were less dramatic. Neither folic nor folinic acid had any effect on the serum vitamin B₁₂ value of patients with pernicious anaemia or of patients with megaloblastic anaemia due to folic acid deficiency. Very large doses of vitamin B₁₂ at the commencement of treatment are recommended to replenish the depleted tissue stores; for maintenance 40 μg . every 10 days or 160 μg . every 21 days was considered to be the minimum effective dose.—L. Wills.

BAUMGÄRTEL, T. and ZAHN, D. Über den Einfluss der Darmflora auf das Vitamin B₁₂. [Influence of the intestinal flora on vitamin B₁₂.] *Klin. Wochenschr.*, 1953, 31, 619-620. [Lab. Coliforsch., Munich.]

Vitamin B₁₂ was added to cultures of *Bacterium coli*, *Bacterium lactis aerogenes* or *Streptococcus faecalis* to produce different final concentrations. The higher concentrations inhibited growth and in time proved fatal, but the lower concentrations did not inhibit at all the growth of *B. lactis aerogenes*

N.A. and R., January 1954

during the period of observation, and only slightly that of the other organisms. These findings, and the fact that in untreated cases of pernicious anaemia from 70 to 95 per cent. of an oral dose of vitamin B₁₂ is excreted in the faeces, but when the vitamin is given with intrinsic factor only from 5 to 30 per cent. is lost, show that vitamin B₁₂ is not destroyed by these intestinal organisms, which are present in the stomach and small intestine as well as in the large intestine of patients with pernicious anaemia.—L. Wills.

1119

BLOQUIAUX, S. Vitaminémie B₁₂ chez les sujets sains ou atteints de dermatoses allergiques. [Vitamin B₁₂ in the blood in health and in allergic dermatoses.] *C.R. Soc. Biol.*, 1953, **147**, 713-716. [Lab. Microbiol. Gén., Univ. Liège.]

Vitamin B₁₂ was estimated with *Lactobacillus leichmannii* in the blood of 10 normal subjects and of 9 with eczema or erythroderma. The normal values ranged from 1.03 to 1.55 µg. per litre and those for patients with dermatitis from 0.85 to 8.25. It was thought possible that the abnormally high values were due to substances other than vitamin B₁₂ which stimulated growth of *L. leichmannii*, and it was observed that very small amounts of histamine stimulated the growth of the micro-organism in the presence of suboptimum amounts of vitamin B₁₂.—A. M. Copping.

WATKIN, D. M., LANG, C. A., CHOW, B. F. and SHOCK, N. W. Agewise differences in the urinary excretion of vitamin B₁₂ following intramuscular administration. *J. Nutrition*, 1953, **50**, 341-349. [Sect. Gerontol., Nat. Heart Inst., Nat. Inst. Health, Bethesda, Md.]

The urinary excretion of vitamin B₁₂ in the 24 hr. after a single intramuscular injection of 20, 30, 50 or 75 µg. of the vitamin was studied in 107 men of widely spread ages. The older men were free from clinically apparent liver or kidney disease, or diabetes. *Lactobacillus leichmannii* was the test organism and amounts above 0.01 µg. could be estimated by the method. In a preliminary test with 19 young men of average age 29.7 and 16 men of average age 76.4 years, significantly more vitamin B₁₂ was excreted by the young men at all levels of administration. In a second study a young group of average age 28.0 years, a middle-aged group of 61.1 years and an old group of 81.6 years excreted less of injected vitamin B₁₂ with increasing age. The decrease was related to the decrease in efficiency of renal function with rising age, but the effect could not be related to renal function alone.—A. M. Copping.

THOMSON, R. M. Megaloblastic anaemia associated with enterocolic anastomosis: report of a case responding to vitamin B₁₂. *Glasgow Med. J.*, 1953, **34**, 270-274. [Royal Infirmary, Glasgow.]

No case has been previously described in which macrocytic anaemia ensuing from enterocolostomy has been effectively treated with vitamin B₁₂.

The operation took place 9 years previously. A single injection of Anahaemin produced a good reticulocyte response but the blood picture soon again deteriorated. The next injection was of 40 µg. vitamin B₁₂. It produced another good response which was maintained with further injections of the same amount.

By operation, the original anastomosis of the gut was undone and the non-functioning but healthy loop of the ileum was restored to continuity. The blood picture was subsequently satisfactorily maintained without further treatment.—E. M. Hume.

1122

SWENDSEID, M. E., HALSTED, J. A. and LIBBY, R. L. Excretion of cobalt⁶⁰-labeled vitamin B₁₂ after total gastrectomy. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 226-228. [Veterans Admin. Centre, Med. Centre, Univ. California, Los Angeles.]

When 0.5 µg. vitamin B₁₂ labelled with ⁶⁰Co was given by mouth to 4 patients after total gastrectomy, all the radio-activity was recovered from the faeces within 4 days. If 50 or 100 ml. gastric juice were given with the vitamin B₁₂ the proportion excreted in the faeces was from 6 to 18 per cent., an amount of the same order as in normal subjects.—A. M. Copping.

1123

CORDA, G. Modificazioni nell'eliminazione dei corpi creatinici in distrofici muscolari durante il trattamento con vit. B₁₂.] **Modification in the elimination of creatine bodies in muscular dystrophy during treatment with vitamin B₁₂.** *Boll. Soc. ital. Biol. sper.*, 1952, **28**, 1935-1937. [Clin. Pediat., Univ. Sassari.]

Creatine and creatinine were estimated daily in the blood of two brothers of 12 and 4 years, and of a girl of 5, with severe muscular dystrophy, before and during daily intramuscular injection of 30 µg. vitamin B₁₂, given for 2 periods of 12 days with a 7 days' interval. For a third period of 8 days an intramuscular injection of 0.5 g. choline was given in addition twice daily. In the boys there was some decrease in the values for creatine and increase in those for creatinine; the effect was more pronounced, and the approach to the normal was greater, when choline also was given.

In the girl the departure from normal values was slight, and little effect was seen.

There was no clinical improvement.

E. M. Hume.

Vitamin C

1124

KIRK, J. E. and CHIEFFI, M. **Vitamin studies in middle-aged and old individuals. 11. The concentration of total ascorbic acid in whole blood. 12. Hypovitaminemia C. Effect of ascorbic acid administration on the blood ascorbic acid concentration.** *J. Gerontol.*, 1953, 8, 301-304; 305-311. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

11. Sixty-one men and 81 women, aged from 40 to 103 years, living in an institution, received a diet containing 45 mg. ascorbic acid daily. Ascorbic acid was estimated in fasting blood and the values were compared with those for subjects aged from 16 to 39 years taking a self-selected diet. In the men, the values decreased significantly from 0.59 mg. per cent. at ages from 40 to 59 to 0.33 at ages from 80 to 103. Values in women were 0.48 in the age group from 40 to 59 and 0.40 in the age group from 80 to 87, but the difference was not significant. Average values for young men were twice as high as for old men, and for young women two and a half times as high as for old women. A possible correlation is suggested between the degree of debilitation in old subjects and the concentration of ascorbic acid in the blood. The men were generally more debilitated than the women.

12. Ten men of average age 70 years and 9 women of average age 64 years, with an average blood ascorbic acid value of 0.26 mg. per cent., received 100 mg. ascorbic acid daily for 14 weeks. Blood ascorbic acid was estimated after 2, 5, 10 and 14 weeks, and 2, 4 and 8 weeks after discontinuation of treatment. In 16 of the patients there was a marked rise in the value, the maximum of 1.15 mg. per cent. being reached after 5 weeks. When the treatment was discontinued the values fell, reaching 0.31 mg. per cent. after 8 weeks. In the 3 remaining cases, there was no rise; in one of them the blood value rose to between 1.27 and 1.57 mg. per cent. when the daily oral dose of ascorbic acid was increased to 300 mg., but with as much as 1000 mg. daily there was no rise in the others; in all three, parenteral administration of 200 mg. 3 times weekly effectively increased the blood values.

The significance of low values for blood ascorbic acid in the aged is not established, and there is no definite indication at present for treatment since the low values are not accompanied by scurvy or other clinical signs.—V. R. Jackson.

JOLI DELPINO, A., M. **Ascorbinuria en el ciclo menstrual, embarazo y climaterio. [Ascorbic**

N.A. and R., January 1954

acid in urine in the menstrual cycle, in pregnancy and in the menopause.] *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 468-486. [Lab. Serv. Sanidad Militar., Univ. Nac. Mayor de San Marcos, Lima.]

The results of studies in Bombay by Pillay (Abst. 890, Vol. 10) are discussed. The urinary excretion of ascorbic acid in 6 young women having a diet rich in ascorbic acid was measured by the indophenol method through several menstrual cycles. The maximum retention and minimum excretion occurred between the thirteenth and seventeenth days of the cycle. The relation of this to ovulation time is discussed. In 5 pregnant women and in one at the time of the menopause no marked retention of ascorbic acid occurred during a 30 days' study and there was little variation in the amount excreted.

A. M. Copping.

1129

NORIEGA PANCORVO, E. Influencia de la insulina sobre la ascorbinemia del diabético. [Effect of insulin on blood ascorbic acid in diabetics.] *An. Fac. Farm. Bioquim., Lima*, 1951, **2**, 335-404 [344]. [Lab. Hosp. Militar "San Bartolomé", Univ. Nac. Mayor de San Marcos, Lima.]

Some preliminary experiments indicated that when insulin was incubated with guineapig blood it had no effect on the ascorbic acid content of the blood, as estimated by indophenol titration.

In human subjects the amounts of ascorbic acid in the blood of normal and diabetic persons were within the same range before insulin was given to the diabetics, but after a dose of 10 units there was a decrease of from 19 to 39 per cent. in the value. The values rose to within the normal range when insulin was discontinued for 3 days. There was no apparent correlation between the values for blood sugar and ascorbic acid in diabetic patients.

Vitamin D

1133

FOLLIS, R. H. (Jr.), PARK, E. A. and JACKSON, D. The relationship of vitamin D administration to the prevalence of rickets observed at autopsy during the first two years of life. *Bull. Johns Hopkins Hosp.*, 1953, **92**, 426-443. [Dept. Paediat., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

A high incidence of rickets had been found at histological examination of the bone in 1303 children coming to autopsy in the first 2 years of life (Abst. 3524, Vol. 23). The same set of data was analysed to ascertain the intake of vitamin D by the children. Much of the data was necessarily of doubtful accuracy, and the analysis was confined to data from children whose histories were deemed reliable.

Of 147 full-term children from 1 to 24 months old, having had no vitamin D, rickets was present in 102, being moderate or severe in 74. Further analysis showed that, in those with and without rickets, the duration of the terminal illness, the state of nutrition, and the month of death, were about the same, but the histological picture of the costochondral junctions showed that in one-third of those without rickets little growth had occurred.

Rickets was present in 12 of 16 premature infants, aged from 1 to 6 months, given no vitamin D. The proportion was about the same as in full-term infants of the same ages.

There were 107 full-term children who had received vitamin D while in hospital for from 7 to 20 days or for more than 20 days. Generalisation was very difficult, but there was a larger proportion with severe rickets among those treated for the shorter period; in some there was healing.

Among 30 premature infants up to 6 months old, who had received vitamin D for varying periods, 22 had rickets.

It is considered probable that the individual requirement of vitamin D is one of the chief variables.—E. M. Hume.

SCHMUZIGER, P. Familiärer persistierender Phosphatdiabetes mit D-Vitamin-resistenter Rachitis (Befunde an zwei Milchzähnen). [**Familial persistent phosphate loss with rickets resistant to vitamin D. Findings on two milk teeth.**] *Helv. paediat. Acta*, 1953, **8**, 276-279. [Chirurg. Abt., Zahnärztl. Inst., Univ. Zürich.] French, Italian and English summaries.

Two milk teeth were examined which had dropped out spontaneously at the age of $3\frac{1}{2}$ from one of the subjects described by Fanconi and Girardet (Abst. 2880, Vol. 22). External signs of rickets were absent from the teeth; there was no hypoplasia and no root resorption. Examined microscopically the enamel and dentine were grossly underdeveloped, and the interglobular substance was poorly calcified. There was no evidence of cessation of the pathological process, which was most active in the layers of dentine formed last.—E. M. Hume.

1136

LORENZINI, R. Ipercalcemia da carico di CaCl_2 e da vitamina D_2 in portatori di gerontoxon ed in rapporto all'età. [**Blood calcium after test administration of CaCl_2 and of vitamin D_2 in patients with arcus senilis and in relation to age.**] *Acta gerontol.*, 1953, **3**, No. 2, 3-12. [Ist. Clin. Med., Univ. Modena.] English and French summaries.

Ca was estimated in the blood serum of 41 male subjects, 20 normal and 21 showing *arcus senilis*. The normal subjects included 4 of mean age 23, 5 of mean age 51, and 11 of mean age 67. The subjects with *arcus senilis* included 8 of mean age 38, and 13 of mean age 64. A dose of CaCl_2 was given intravenously, supplying 0.182 g. Ca, and estimations were made beforehand and after 3, 30 and 90 min. On the next 3 days an intramuscular injection of 15 mg. vitamin D_2 was given, and on the last of these the response to injection of CaCl_2 was tested again. In the subjects without *arcus senilis* the curve of response was somewhat higher the greater the age. After administration of vitamin D_2 the curves bore the same relation to one another, but were all at a somewhat higher level. In the subjects with *arcus senilis* the effect was the same, but the curves lay at a higher level than in those without, and the rise caused by vitamin D_2 was greater.

1137

JONXIS, J. H. P. and HUISMAN, T. H. J. **Amino-aciduria in rachitic children.** Amino-acidurie bij rhachitische kinderen. [**Amino-aciduria in rachitic children.**] *Lancet*, 1953, **265**, 428-431; *Voeding*, 1953, **14**, 400-407. [Kind-erklin., Acad. Ziekenhuis, Groningen.]

It had been shown that children with rickets excrete in the urine more than the normal amount of α -amino-acids (Abst. 2280, Vol. 23), and it was sought to ascertain the nature of the amino-acids contributing to the increase. Detailed studies were made on 5 children, 2 with ordinary rickets, 1 with resistant rickets and 2 normal controls. The children with rickets were chosen for the study as representing typical classes of rachitic children; the first at 8 months of age normally fed but without vitamin D, the second, at 7 months of age, fed on milk only and without vitamin D, the third, 4 years old, admitted for the second time with resistant rickets, for which he had in the past received 100,000 I.U. vitamin D_3 daily for 10 days.

During the test period, diet was uniform and the chief source of protein was 500 ml. cow's milk. Urine amino-acids were estimated by chromatography on the cation exchange resin Dowex 50. Complete separation was not achieved between threonine and serine, between glycine and alanine, or between tyrosine and phenylalanine. Total urine amino-acids in mg. per 24 hr. for the 5 children in the above order were 453, 754, 898, 311 and 263 before treatment, and after administration of vitamin D_3 , a single dose of 300,000 I.U. to the first and second and 1 million I.U. daily for 16 days to the third child, 265, 590, 709. The normal children received no vitamin D.

The high excretion of amino-acids was due to threonine and serine, glycine and alanine, histidine, lysine and bound glutamic acid. The children with ordinary rickets excreted no cystine before or after vitamin D_3 ; the others did. Only the first child showed normal excretion in general after treatment; in the second, loss of glutamic acid continued high, and in the third it increased.

Comparison of the amino-acid in ultrafiltrates from plasma of a normal and a rachitic child showed nothing abnormal in rickets. Tubular re-absorption was tested in 3 normal and 3 rachitic children with intravenous injection of histidine and arginine. Of the injected amounts the normals excreted 3.6 per cent. of histidine and 0.2 per cent. of arginine; the patients 32.5 and 0.3 per cent.

Further studies showed that other members of the family of the second child were excreting an excess of amino-acids and that the resistant rickets of the third was familial also. The quantities of the chief amino-acids lost were not serious in relation to the amounts supplied in the food.

The results are discussed in relation to theories of rickets and other disorders in which failure of re-absorption of amino-acids occurs, such as cystinuria. It is suggested that the excessive loss of alanine and glycine is in some way connected with the failure of tubular re-absorption of P in rickets.—I. Leitch.

1138

SALVESEN, H. A. and BÖE, J. **Osteomalacia in sprue.** *Acta med. scand.*, 1953, **146**, 290-299. [Med. Clin. B, Rikshosp., Univ. Oslo.]

Of 85 patients with sprue, 40 had the serum levels of Ca or P or both so far reduced that the Ca \times P product fell below 27, and a chemical diagnosis of osteomalacia was made. Radiography showed bony changes in 22 of the 40; 4 had Milkman's pseudofractures, 3 late rickets and the rest osteoporosis. In the 7 with marked bony changes the value for serum phosphatase was high, for serum Ca slightly reduced, and for serum P considerably reduced. In 3 patients with tetany and osteoporosis the serum phosphatase levels were normal but those for serum Ca and P were low, and the Ca \times P product was very low; in spite of the low product, bony changes were slight. The remaining 12 patients with bony changes showed osteoporosis but not tetany, though the blood findings were like those in patients with tetany. All the patients responded to vitamin D. For comparison with the patients with bony changes, 12 without bony change were studied; all had low serum Ca values but normal ones for serum phosphatase and P, and 7 suffered from tetany. On treatment with vitamin D the value for Ca rose but not for P. A low serum P in the patients with bony lesions was considered evidence of hyperparathyroidism which, in those with low serum Ca, was not sufficient to mobilise enough Ca from the bones to protect from tetany. In those without bone lesions normal P and low Ca values in the serum were considered evidence of hypoparathyroidism, the possible cause of which is discussed.—L. Wills.

1139

KÖBL, H. Ekzembehandlung mit Vitamin D. [Treatment of eczema with vitamin D.] *Wien. klin. Wochenschr.*, 1953, **65**, 524-528. [Kind-erklin., Univ. Vienna.]

Twelve infants in the first 18 months of life, with severe weeping eczema, were injected intravenously with a special aqueous preparation of vitamin D₂ (Wander), a total of from 15 to 30 mg. being given within 12 days. There was dramatic healing in all except one to which physiological saline was given with the vitamin. The mode of action is discussed, and it is recommended that a salt-free diet should accompany the treatment but that a diet low in protein is not necessary.

FERSTL, A. and LACHNIT, V. Die Gefahren der Dicumarintherapie während der Lactation. [The dangers of dicoumarol treatment during lactation.] *Klin. Wochenschr.*, 1953, **31**, 539-541. [2. Med. Klin., Univ. Vienna.]

The anticoagulant content of human milk was estimated in 6 lactating women with a daily output of milk ranging from 150 to 1500 ml. after a single oral dose of 900 mg. 3:3-ethylidene-bis-4-oxy-coumarin. Blood prothrombin, total milk output and dicoumarol output in milk and urine were estimated daily for 5 days after administration of the test dose, no other medication being given. The mean dicoumarol content of the milk on the first day was 297 μ g. per ml., range 266 to 326; the highest concentration was found in milk from the subject with the smallest secretion. The values for milk were 10 times higher than for serum, possibly because at 37° C. serum is saturated with dicoumarol at a concentration of about 50 μ g. per ml., and human milk at one of about 450 μ g. per ml. The concentration decreased in the milk during the 5 days of observation, but in 2 patients with a very low total secretion it was still high at the end of this period. In these 2 subjects the urinary output was low; in the others it was high on the first day and fell gradually during the next 4 days. The blood prothrombin value fell to a minimum on the second or third day and had returned to normal by the fifth day in all the subjects. The larger the total output of milk the greater the loss of dicoumarol in it, and the smaller

the fall in the blood prothrombin value, so that the larger the milk output the larger the dose of dicoumarol required to produce the desired fall in the blood prothrombin level. The findings show the risk to a nursing infant of receiving an overdose of dicoumarol if the mother is being treated with it, and are a contra-indication for oral administration of dicoumarol during lactation.

DENTAL DISEASES

1144

CAMERON, D. A. **An investigation of the caries experience and diet of groups of school and pre-school children in Sydney (1946-1947).** *Dent. J. Austral.*, 1953, **25**, 50-56. [Inst. Dent. Res., Chalmers St., Sydney.]

The occurrence of dental caries in 1044 children 2 to 12 years was recorded in conjunction with dietary survey data obtained by the questionnaire method from 906 of the subjects. The information got from the dietary records was not entirely satisfactory, but from it a picture was drawn of the type of diet scale to which the children were accustomed and a comparison was made, in general terms, with recommended allowances.

Only 11 per cent. of the children, all of whom were below 8 years of age, were free from caries. Maximum values of 12.6 and 13.6 for the mean number of DMF teeth per child for boys and girls were reached at 8 and 7 years, respectively, and of 19.1 and 19.0 for DMF surfaces per child for boys and girls at 6 and 7 years of age.

The view that too high a proportion of energy comes from refined carbohydrates is expressed and discussed in relation to other published work.

1145

DEMOLE, V. and HELD, A. J. **Fluor et santé générale. État de santé de la population autochtone et immigrée du village de Sembrancher. [Fluorine and general health. State of health of the native and immigrant population of the village of Sembrancher.]** *Schweiz. med. Wochenschr.*, 1953, **83**, 362-364. [Lausanne.]

The population examined consisted of 750 persons, mostly indigenous but including a small group of labourers and their families who had immigrated into the valley from 9 to 19 months before the study was made. These people and, in the case of the natives, their forebears as well, used a water supply containing from 1 to 1.4 mg. F per litre. No evidence could be obtained of any toxic effect; the incidence of otosclerosis, enlargement of the thyroid gland and rheumatism was not greater than in the general population. The incidence of dental caries was low; there was no mottling of enamel.—L. Wills.

1146

CLAPPER, W. E., DOWNS, R. A. and HEATHERMAN, M. E. **The relation of caries activity to lactobacillus counts and types and to the fluoride content of drinking water. 2. Results of examinations made after a one-year interval.** *J. Dent. Res.*, 1953, **32**, 440-444. [Dept. Microbiol., Univ. Colorado Sch. Med., Denver.]

A re-examination was made of 312 of 383 children in Denver, an F area, and in Boulder, an F-free area, and from the saliva of 73 and 70 in these areas, respectively, lactobacilli were isolated, counted and typed (see Abst. 5061, Vol. 23). There was evidence that of the Denver children, with 1 p.p.m. F in their drinking water, who were caries-free at the previous examination, those with high counts of rhamnose-fermenting lactobacilli were more likely to develop caries than those in the same area but without that type of organism. Where there was no F in the water, caries appeared in nearly all the children, irrespective of the type or number of organisms. Fluoride in the amount of 1 p.p.m. F in the water was without effect on the type of organism which became established.

D. Harvey.

1147

MITRANI, R. M. **El fluor como preventivo de la caries dental. [Fluorine as preventive of dental caries.]** *Bol. Ofic. sanit. panamer.*, 1953, **34**, 245-255. [Havana, Cuba.] English summary.

The evidence for the value of F in drinking water as a preventive of dental caries is discussed with reference to studies of the problem in North America. The effects of addition of fluoride to drinking water and of the topical application of fluorides to children's teeth are considered. In Cuba, where the F content was not above 0.4 p.p.m. in 250 samples of water examined, the incidence of dental caries is estimated to be 95 to 98 per cent. The cost of adding F to raise the content to 1 p.p.m. was calculated to be very low relative to the benefits likely to accrue. An alternative suggestion was the topical application of fluoride to children's teeth at the ages of 3, 7, 10 and 13 years, but this would probably cost more.

1148

OCKERSE, T. **Chronic endemic dental fluorosis in Kenya, East Africa.** *Brit. Dent. J.*, 1953, **95**, 57-60. [Union Health Dept., South Africa.]

At 4 centres where European children were examined 112 were found with mottled enamel. Asian and African children were more permanently resident in their particular districts than were Europeans and when the percentage incidences were calculated for the 712 Asian and 592 African children examined they were 67 and 47 per cent.,

N.A. and R., January 1954

respectively. The degree of mottling, which varied from questionable through very mild, mild and moderate to severe, was in most cases only very mild or mild. There was evidence that the F content of the supplies of drinking water, which are mainly from recent volcanic strata, was excessive. The incidence of dental caries was very low.—D. Harvey.

1149

SATYANARAYANA MURTHI, G. V., NARAYANA RAO, D. and VENKATESWARLU, P. **Studies of endemic fluorosis (Visakhapatnam and suburban areas) : spinal compression due to skeletal fluorosis.** *J. Indian Med. Assoc.*, 1953, **22**, 396-399. [Andhra Med. Coll., Visakhapatnam.]

The finding of advanced fluorosis in an adult man, clinical details of which are given, prompted examinations of the population of the district for "stiff-back" and of their water supplies for F. A range from 1.2 to 11.0 p.p.m. F was found in samples from 17 sources of supply. The patient and his neighbours, in whom signs of fluorosis were not so common as had been expected, had been consuming water with a content near the upper level, but where it was less than 3.8 p.p.m. "stiff-back" was unknown. It is concluded that an amount up to 4 p.p.m. is not hazardous.

D. Harvey.

1150

VENKATESWARLU, P., NARAYANA RAO, D. and RANGANATHA RAO, K. **Studies in endemic fluorosis : Visakhapatnam and suburban areas. Fluorine, mottled enamel and dental caries.** *Indian J. Med. Res.*, 1952, **40**, 535-548. [Dept. Biochem., Andhra Med. Coll., Visakhapatnam.]

Investigation of the water supplies in the Visakhapatnam area is proceeding, and in 39 localities the F content has been found to range from traces to 11.0 p.p.m. In 12 villages where it ranged from 0.3 to 1.6 and averaged about 1 p.p.m. records were made of the teeth of 1009 children according to a scheme based on the Evanston Study (Abst. 3626, Vol. 18). Calculations were also made of a dental fluorosis index for each district from the degree of mottling and its frequency of occurrence.

The general relationship between incidence of caries and F content of drinking water was confirmed, but in 6 villages with nearly the same amounts of between 0.8 and 1.0 p.p.m., the DMF rate was found to range widely for the age group 7 to 9 years. There existed also in these villages a marked variation in the incidence of mottling; in 2 villages each with 0.9 p.p.m. the incidences were 5 to 45 per cent. In general where F contents were similar caries fell in amount

as the dental fluorosis index rose. In 1 exceptional community a low incidence of mottling was associated with a low incidence of caries, a finding which lent support to the hypothesis of Dean *et al.* (Abst. 3646, Vol. 9).

Seven years before the study the population of one village had migrated from an area where the F content was 1.6 to another where it was between 0.5 and 0.8 p.p.m. Among the children born after the movement who at the time of examination were from 3 to 6 years of age there was both a high incidence of mottled enamel and a high resistance to caries, from which it is concluded that transmission of F across the placenta and by way of the mammary gland may influence the incidence of both defects in the young child.

1151

KUTLER, B. and IRELAND, R. L. **The effect of sodium fluoride application on the dental caries experience in adults.** *J. Dent. Res.*, 1953, **32**, 458-462. [Coll. Med., Univ. Nebraska, Omaha.]

Adult students numbering 147 with age range 20 to 42 and mean age 24 years had 2 quadrants of their mouths treated with 4 applications of a 2 per cent. solution of NaF. Re-examination was made about 13.5 months later. There was no significant difference in the incidence of new caries in the treated and untreated quadrants, nor was there any significant reduction in the incidence of caries on the basis of total new caries.

D. Harvey.

1152

WINKLER, K. C., DIRKS, O. B. and VAN AMERONGEN, J. **A reproducible method for caries evaluation-test in a therapeutic experiment with a fluorinated dentifrice.** *Brit. Dent. J.*, 1953, **95**, 119-124. [Lab. Hyg., Univ. Utrecht.]

The reproducibility of evaluation by a method previously described (Title 3142, Vol. 21) was tested with a longer interval between the X-ray photographs, 18 months instead of 14 days in the earlier investigation. Over this period reproducibility was again found to be good.

During the period 2 comparable groups of boys of 11 to 15 years of age used the same basic dentifrice, which was fluoridated for the one and fluorine-free for the other, and the effects on approximal caries in premolar and molar regions were examined. In the fluoridated paste total F amounted to 650 $\mu\text{g.}$ per g. and soluble F to 335 $\mu\text{g.}$ per g. and a mean amount of 0.75 g. was used daily by each boy. There was no prophylactic value which could be attributed to the F in the paste.

An extension of the investigation to anterior teeth is in progress.—D. Harvey.

1153

ADLER, P. and STRAUB, J. **A water-borne caries-protective agent other than fluorine.** *Acta med. hung.*, 1953, **4**, 221-227. [Dept. Stomatol., Med. Sch., Univ Debrecen.] Russian summary.

Generally speaking, field studies in Hungary have confirmed the caries-protective effect of drinking waters containing about 1 p.p.m. F (Abst. 4110, Vol. 21). Nevertheless, the results for 2 communities in the Hungarian plain about 15 km. apart, served by a number of artesian wells, were discrepant, that with the water of lower F content, from 0.13 to 0.60 p.p.m. having a surprisingly low incidence of caries among the schoolchildren. Since the populations were similar in race, socio-economic status and food habits, it is suggested that the waters in the favoured district contain some unknown substance, probably a trace element other than F, with a direct caries-preventing effect.

SMITH, E. B., WOLLAEGER, E. E. and VICTOR, M. **Tolerance to nasogastric tube feedings. A comparative clinical study of two dietary formulas.** *Arch. Int. Med.*, 1953, **91**, 721-728. [Mayo Found., Rochester, Minn.]

The literature shows great variation in the com-

position of fluids recommended for tube feeding, without much evidence on their merits or demerits in use. Owing to the frequent occurrence of diarrhoea among patients receiving a standard tube-fed diet which had been in use in the Mayo Clinic for 5 years, a test was made with 74 patients, mostly with brain lesions, over a period of 7 months in which alternate patients received the standard mixture or a differently proportioned but isocaloric one, both by nasogastric drip under standardised conditions. The standard mixture contained, in g., evaporated skimmed milk 1000, skimmed milk powder 200, egg yolks 100, sugar 100, salt 3.5, with water and a vitamin supplement and supplied, in g., protein 158, fat 34 and carbohydrate 305, of which 204 was lactose. The alternative contained, in g., whole milk 1000, skimmed milk powder 90, whole eggs 200, Dextrin-Maltose No. 1, 100, 20 per cent. cream 200, salt 3, with the vitamin supplement, and supplied, in g.,

N.A. and R., January 1954

protein 98, fat 103 and carbohydrate 205, of which 104 was lactose. Both had a total volume of 1500 ml., supplying 2150 Cal. per 24 hr.

Of 30 patients on the alternative, only 3 had diarrhoea; of the 27 who did not, 10 had had it previously when on the standard diet. Of 44 patients on the standard mixture, 17 had diarrhoea, and it was concluded that this far outweighed any possible advantage of the higher protein content of this diet. It is not clear whether the poor tolerance is due to its high protein or high carbohydrate content, to the large amount of lactose, or to the unbalanced proportions of the constituents.

1164

ELLIOTT, J., GRIFFITHS, J. J., SMITH, D. W., LEWIS, G. T. and FERRO, P. V. **Continuous enteral feeding and its importance in protein metabolism of the sick.** *Southern Med. J.*, 1953, **46**, 572-578 (with discussion 578). [Med. Res. Found., Dade County, Miami, Fla.]

The increased protein requirement in illness is discussed and the difficulty of supplying it by intermittent feeding. A method was developed by which a sterile solution of enzymic protein digests with added soluble carbohydrates was administered by continuous drip through a plastic tube of outside diameter 2 mm. The tube was passed through the nose into the upper intestinal tract and was well tolerated by patients. A brief analysis is given of results with 869 patients, showing the value and applicability of the method. The inclusion of vitamins in the sterile solution is not recommended; they should be given separately when required.—A. M. Copping.

SHITERI, P. K. and HIGHLAND, G. P. **Excretion and retention of two modified gelatins in normal human beings.** *J. Appl. Physiol.*, 1953, **5**, 814-820. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

In the search for a gelatine which in solution would not gel at ordinary temperatures and could therefore be used in the field for treatment of casualties, 2 materials were tested. Oxypolygelatine was prepared by the method of Campbell *et al.* (*Texas Rep. Biol. Med.*, 1951, **9**, 235) and is liquid in 5 per cent. solution in 0.9 per cent. NaCl solution at room temperature. A "fluid gelatine" was prepared by treating gelatine with a dicarboxylic acid anhydride under specified conditions of pH and temperature. This is liquid in 3 per cent. solution in 0.7 per cent. NaCl solution at room temperature. When 500 ml. of these solutions were infused during 1 hr. into men convalescing from minor burns at the end of 6 hr. the "fluid gelatine" gave significantly greater plasma retention and smaller urinary excretion than the oxy-

polygelatine. With both materials the greatest urinary excretion occurred within 6 hr. from the start of infusion. Gelatine in plasma or urine was measured by estimating hydroxyproline after hydrolysis with 6N HCl in a sealed tube at 150° C.

MÜLLER, K. and TÄUFEL, K. **Zur Veränderung von Traubenzucker- und Invertzuckerlösungen bei der Erhitzung (Sterilisation). [Changes in dextrose and invert sugar solutions on heating (sterilisation).]** *Biochem. Ztschr.*, 1953, **324**, 221-227. [Inst. Ernährungsforsch., Potsdam, Rehbrücke.]

Tests by paper chromatography of dextrose and invert sugar solutions sterilised for intravenous use showed that reversion took place in the fructose fraction of the invert sugar but not in the dextrose solution. In the chromatogram of Calorose preparations (invert sugar), 3 ketose-containing, non-reducing reversion products with different R_F values were visible. Comparative chromatographic experiments showed that when fructose solutions were heated, different kinds of reversion products were produced, according to the experimental conditions. From the R_F values these might be mainly difructose-dianhydrides. The reversion products seem to be stable, and to undergo no change in the storing of Calorose.

The senior author's system of combining clinical and laboratory findings so as to allow a post-prandial blood sugar level between 170 and 240 mg. per 100 ml. if this is compatible with the patient's wellbeing is considered in detail (see Abst. 3500, Vol. 16). Data obtained from 2 groups each of 100 patients are given in full, and they support the conclusion that such hyperglycaemia is not necessarily harmful and may even be protective. The latter part of the paper is of the nature of a review article on arteriosclerosis, the state of the islets of Langerhans and retinopathy in diabetes, with a concluding section on the general interpretation of the disease. There is a bibliography with 113 references.—D. Harvey.

GIRDANY, B. R. Peptic ulcer in childhood. *Pediatrics*, 1953, **12**, 56-61. [Dept. Paediat., Sch. Med., Univ. Pittsburgh, Pa.] Spanish summary.

In 45 children between the ages of 14 months and 11 years, 25 girls and 20 boys, the diagnosis of peptic ulcer was made on clinical and radiological grounds. Recurrent pain was usual, but 4 children complained of vomiting only. Emotional disturbances were often present. It is suggested that peptic ulcers are frequent in childhood and that there is probably a strong psychogenic element in their causation.—M. S. Fraser.

- LEVIN, M. B. and GWYNN, B. A. **Therapy of gastro-duodenal ulcerations.** *Amer. J. Digest. Dis.*, 1953, **20**, 187-194. [Baltimore, Md.]

Estimation of the percentage of meat fibre digested by examination of stools as a diagnostic measure and reduction and control of meat digestion as a therapeutic measure in peptic ulcer patients are described.

The treatment outlined consists in the use of antidiigestant and antispasmodic drugs and control of diet. Recommended are 3 meals a day, plenty of animal protein and non-insistence on mincing or puréeing of all foods.—F. C. Aitken.

1185

- FRADKIN, W. Z. **The dietary treatment of diarrheal diseases.** *Amer. J. Digest. Dis.*, 1953, **20**, 208-210. [Brooklyn, N.Y.]

A diet is described which is recommended for use in the treatment of diarrhoea.

The beneficial effect of carob flour in the treatment of diarrhoea in adults was demonstrated in studies of 50 patients. Tests on 3 patients showed that its ingestion did not interfere with absorption of antibiotics.—F. C. Aitken.

1186

- FORTIER, DE LA B., LEBEL, G. and FRÉCHETTE, A. La thérapeutique des diarrhées infantiles et la farine de caroube. [Treatment of infantile diarrhoea with carob meal.] *Laval méd.*, 1953, **18**, 745-759. [Hôp. Enfant-Jésus, Quebec.]

During 1950 to 1952, 253 infants with diarrhoea, 75 per cent. of them below the age of 7 months and 16 per cent. newborn, were treated with a preparation of carob meal (Arobon, Nestlé); no other treatment was given. All patients with diarrhoea, including severely toxic and complicated cases, were treated. The total mortality was 9.09 per cent. Of the 23 fatal cases, 12 died after the cessation of treatment from complications such as mastoid disease and congenital heart

disease; of the other 11 fatal cases, 4 were excluded from consideration, death being due to causes other than the diarrhoea; the remaining 7 died with toxic signs, but in only 3 was the diarrhoea not controlled. Formed stools were obtained in a mean time of 1.8 day, but to prevent relapse it was generally necessary to continue treatment for from 6 to 8 days, when the carob meal could be replaced by other foods.—L. Wills.

1192

- KELLY, F. C. **Studies on the stability of iodine compounds in iodized salt.** *Bull. World Health Organiz.*, 1953, 9, 217-230. [Chilean Iodine Educat. Bur., London.] French summary.

The chief conditions which adversely affect the stability of I in salt are moisture, light, heat, impurities and acidity. If the salt mass is not dry the iodide may migrate from one area in the container to another and even into the fabric of the container if that is made of absorbent material. Lacquered tins with impervious linings are suitable for storage of iodised salt. Exposure to sunlight is accompanied by loss of I if the salt is treated with iodide, but not with iodate. Exposure to heat has the same effect if the salt is neutral or acid, but if it is made slightly alkaline with NaHCO_3 or treated with iodate no loss occurs. Currents of air, the presence of impurities and storage under acid conditions all cause loss of I. Salt treated with iodide if dry, free-running, packed in lined impervious cartons, and kept in a cool place and away from strong light, does not lose I and the iodide does not redistribute itself in the mass. In areas where a crude, moist, impure, unprocessed salt is used, treatment with iodate is recommended. Such a product is in use in Mexico.

- MATOVINOVIĆ, J. **The problem of goitre prevention in Yugoslavia.** *Bull. World Health Organiz.*, 1953, 9, 249-258. [Clin. Int. Med., Fac. Med., Zagreb.] French summary.

A region of endemic goitre in Yugoslavia extends from the north-west to the south-east of the country. Statistics are scarce and many are inaccurate but with several interruptions an investigation of incidence has been made since 1923. About 1,400,000 people suffer from the disease. Iodised salt is most urgently needed for prophylaxis. Yugoslavia requires 197,500 tons of salt annually. Salt works in Bosnia produce 68,000 tons, of which only 18,000 tons are iodised,

and the marine salt works supply 62,500 tons, none of which is iodised.—B. W. Simpson.

1195

- NICOD, J. L. **Le goitre endémique en Suisse et sa prophylaxie par le sel iodé. [Endemic goitre in Switzerland and its prophylaxis by iodised salt.]** *Bull. World Health Organiz.*, 1953, 9, 259-273. [Inst. Anat. Pathol., Univ. Lausanne.] English summary.

Recruitment statistics from 1900 to 1925 showed a high incidence of goitre among men from certain regions of Switzerland. Among schoolchildren and hospital patients the incidence was also high. Improvement in the general hygiene of the people was followed by reduced incidence but the decrease was most marked when in 1922 iodised salt was introduced. By 1950 only one canton did not use it, and this region had the highest rate of discharge from the army for goitre. By 1946 no person under 35 years of age had nodular goitre. The dose recommended as optimum was 5 mg. KI per kg. salt, but because of changes in moisture content and conditions of storage there was variation in the intake and as a rule less was consumed. The amount, however, was effective and no harmful effect was noted. The addition of iodate instead of iodide or more efficient desiccation of the salt is recommended.

- WESPI, H. J. **Jodprophylaxe und Jodmangel. Untersuchungen über die Schilddrüsenverhältnisse bei Schulkindern in einigen Schweizer Dörfern. [Iodine prophylaxis and iodine lack. Investigation of the state of the thyroid gland among schoolchildren in certain Swiss villages.]** *Schweiz. med. Wochenschr.*, 1953, 83, 452-458. [Geburtshilf.-Gynäkol. Abt., Kantonsspital, Aarau.]

Iodisation of salt was introduced in Canton Aarau in 1952 and an examination was made of the schoolchildren as a base line for future comparisons on the effect of iodine treatment. In some of the villages examinations had been made 20 and 40 years ago. Children in certain other villages, including some in Canton Zürich where iodised salt had been used for 20 years, were examined also because the incidence of goitre there was very high or very low. The figures are set out and show that, even without I prophylaxis, there has been a gradual fall in incidence of goitre, due probably to improvement in the standard of living, but that where I prophylaxis has been practised for a number of years the reduction of goitre has been much greater. Since, however, there are still those who deny that I lack is the cause of goitre, the evidence in support of that hypothesis is marshalled.—E. M. Hume.

N.A. and R., January 1954

1197

KOPF, H. Für und wider die Jodierung des Kochsalzes. [For and against iodisation of table salt.] *Wien. klin. Wochenschr.*, 1953, 65, 537-540. [Chirurg. Abt., Krankenhaus Barmherz. Schwestern, Linz.]

A comparison is made of the goitre problem over the last 30 years in Switzerland and Austria. In Switzerland iodised salt has been available at the same price as non-iodised salt; in Austria after 1933 it cost more and prophylaxis by means of it very nearly ceased. The almost complete control of goitre in Switzerland is compared with the high incidence reported at different times and places in Austria. The optimum dose and mode of action of iodine, and the varying incidence of hyperthyroidism and neurosis in areas that had or had not received iodised salt, are discussed. The effect of a water supply with a high iodine content is illustrated by reference to the low incidence of goitre in schoolchildren in Bad Hall neighbourhood. Finally, it is claimed that by the use of iodised salt Swiss children have become bigger and more intelligent.—L. Wills.

LAROCHE, G., TRÉMOLIÈRES, J. and VICHNESKY. Enquête sur l'endémie goitreuse. (Département du Lot). [Inquiry on endemic goitre. (Department of Lot).] *Bull. Inst. nat. Hyg., Paris*, 1953, 8, 445-448.

From 4 areas in the Department of Lot 1013 girls and 741 boys between the ages of 7 and 18 years were examined. The 4 areas were of different geological formation, but no significant difference was noted in percentage incidence of goitre. The overall incidence was 37.9 per cent. among girls and 32.1 per cent. among boys. [It has not been possible to reconcile these figures with the data reproduced.]—B. W. Simpson.

1199

RAMALINGASWAMI, V. The problem of goitre prevention in India. *Bull. World Health Organiz.*, 1953, 9, 275-281. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.] French summary.

Goitre, deaf-mutism and cretinism are prevalent in the northern regions of India from the North-West Frontier through Kashmir, Nepal, Bihar and Assam to Burma. The etiology of goitre in these regions is complex and bacterial pollution of drinking waters, excessive intake of Ca, faulty and unbalanced diets may all play their part. In India it is difficult to iodise the coarse crystalline salt obtained by solar evaporation of brine and to stabilise its I under the conditions of humidity and heat which prevail. Indian food habits also

entail loss of I, since salt is not usually taken separately but only added to the food during cooking.—B. W. Simpson.

1200

STACPOOLE, H. H. Prophylaxis of endemic goitre in Mexico. *Bull. World Health Organiz.*, 1953, 9, 283-291. [Nat. Campaign against Endemic Goitre, Mexico.] French summary.

The results of a goitre survey in 8 states of Mexico are discussed. Areas of goitre endemicity were first located and then prophylactic measures were undertaken where possible. All the states bordering the Pacific were implicated, and mid-central and southern parts were also affected. The incidence of goitre was 19 per cent. in more than 1 million persons examined. Fifty-three per cent. of all the cases were slight, 33 per cent. were more than slight, 12 per cent. had large and obvious goitres and 2 per cent. had huge goitres. Cretinism, imbecility and deaf-mutism, as well as other defects, were also frequently encountered in the endemic areas.

Iodised salt containing 1.5 part of KI per 100,000 parts of salt was recommended by the authorities, but the total amount of such salt produced in the country is insufficient for the requirements. Iodised sweets given to 50,000 schoolchildren resulted in a drop of 16 per cent. in incidence. In 1952 the impure moist salt of the district was impregnated with iodate by hand spraying. This product was found to be stable and was successfully used in one village.—B. W. Simpson.

1201

SCRIMSHAW, N. S., CABEZAS, A., CASTILLO, F. and MÉNDEZ, J. Effect of potassium iodate on endemic goitre and protein-bound iodine levels in school-children. *Lancet*, 1953, 265, 166-168. [Inst. Nutrit. Central America and Panama, Guatemala.]

The present study was designed to test the effectiveness of KIO₃ in reducing the incidence of goitre in schoolchildren in an area of high endemicity. The children were 5 to 14 years old; 811 attended 2 rural schools in El Salvador and 197 attended a school in Guatemala. An initial examination showed a goitre incidence of 34 to 57 per cent. The children were divided into 3 groups: one group received tablets containing glucose only, the second group tablets containing 6.5 mg. KI and the third group tablets containing 8.5 mg. KIO₃, which supplied 5 mg. of I weekly, equivalent to the amount ingested when salt is iodised at the level of 1 in 10,000 parts.

During the first 15 weeks, the number of goitres increased by 6 per cent. in the control group, but was reduced by 40 per cent. in the second and by

44 per cent. in the third group. A second trial which lasted 20 weeks showed a similar drop in the incidence of goitre among the children treated with I. At the end of an interval of 16 weeks with no treatment the incidence of goitre had returned to its original value. Renewal of the treatment again reduced the incidence. The necessity for continuous treatment in these areas was realised.

The protein-bound I level of some children in the control group was 2.68 $\mu\text{g.}$, in the KI group 4.97 and in the KIO_3 group 5.1 $\mu\text{g.}$ per 100 ml. There was a definite increase in the treated children over the controls, but no significant difference was found between the group treated with KI and that with KIO_3 .

The conclusion is drawn that KIO_3 given by mouth is a suitable prophylactic for endemic goitre and has several advantages over KI, e.g., greater stability in the presence of impurities and moisture. The need for continuity of the treatment in an endemic area is stressed.

B. W. Simpson.

1202

SALAZAR NORIEGA, S. T. Bocio endémico en el Perú. [Endemic goitre in Peru.] *Rev. Fac. Farm. Bioquim.*, Lima, 1952, 14, 79-85.

In this brief extract from a thesis on endemic goitre in Peru, some numerical data are given. Estimations of total plasma I in 110 normal persons gave averages of 10.13 $\mu\text{g.}$ per 100 ml. on the coast and 7.96 on the Sierra. For 81 goitre patients the averages were 7.46, 9.04 and 5.95 for men, women and children, respectively. In the goitrogenic zones 50 to 60 per cent. of the schoolchildren were affected, and 70 to 80 per cent. of those rejected for military service suffered from physical defects or congenital abnormalities attributable to goitre. It is probable that the incidence of goitre in Peru is 10 times greater than was indicated by the census of 1940. The highest incidence was of diffuse goitre.—M. B. Richards.

Observations are reported on 4 patients with hypertensive vascular disease to whom diets containing 20 to 23 m. equiv. K daily, between $\frac{1}{3}$

and $\frac{1}{4}$ of the normal intake, were given. Not later than 48 hr. after and often within 24 hr. of the diet change there was a small but significant decrease in "resting" blood pressure. Urinary K fell and there was also a decrease, which was more marked, in urinary Na. The diet was, however, unpalatable and, in respect of protein, unbalanced and its use for longer than 3 to 9 days might have had dangerous complicating effects. The observations point again to a relation between certain cations and the hypertensive state.

[Therapeutic-clinical studies of the treatment of chronic kidney disorders with a saltless diet rich in protein.] *Deutsch. Arch. klin. Med.*, 1953, **200**, 86-122. [Med. Klin., Univ. Bonn.]

Twenty-four patients with chronic kidney disorders of different types, on a diet restricted in fluid and salt, were given for some weeks a protein supplement of 150 to 200 g. Aletosal, a low-salt dried milk containing protein 25, fat 27, lactose 40 and minerals 4.5 per cent., including 0.2 per cent. salt. Individual details of blood pressure, fluid balance and albumin in urine, residual N, xanthoproteins and uric acid in blood, and serum protein fractions are tabulated.

The protein supplement had no significant effect on blood pressure, diuresis, albuminuria or subjective symptoms. There was little change in the xanthoprotein content of the blood; uric acid was reduced but residual N rose in some. Changes in protein fractions in blood were slight, and total serum protein rose only in patients whose past circumstances pointed to protein underfeeding. The general conclusion was that treatment with a low-salt, low-fluid, high-protein diet is suitable for patients with negative N balances, and can safely be used even when there is slight renal insufficiency.

- BALCH, C. C., BALCH, D. A., JOHNSON, V. W. and TURNER, J. Factors affecting the utilization of food by dairy cows. 7. The effect of limited water intake on the digestibility and rate of passage of hay. *Brit. J. Nutrition*, 1953, **7**, 212-224. [Nat. Inst. Res. Dairying, Univ. Reading.]

Six cows were fed on 8.2 kg. alfalfa hay daily. During the experimental periods water intake was limited to 60 per cent. of that taken freely. The intake of hay fell and all cows temporarily lost weight, which was replaced when normal water intake was allowed.

During the period of restricted water intake digestibility of dry matter and crude fibre increased slightly, but this did not affect the intake of apparent digestible energy and starch equivalent, because of the lower intake of hay. The rate of passage of stained hay was little affected by reduced water intake.

Studies of the changes in the rumen and reticulum were made during limited water intake on a cow with a fistula. During this period the dry matter in the digesta was maintained at a constant level and there was an apparent increase in the secretion of saliva, favouring fermentation.

- HEAD, M. J. The effect of quality and quantity of carbohydrate and protein in the ration of the sheep on the digestibility of cellulose and other constituents of the ration, with a note on the effect of adding vitamins of the B-complex on the digestibility and retention of the nutrients of a hay ration. *J. Agric. Sci.*, 1953, **43**, 281-293. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Three-year-old Cheviot wether sheep received 500 g. hay daily and a study was made of the effect on the digestibility of cellulose of additions of flaked maize and, if necessary, maize or potato starch to provide half, three-quarters or the full requirement for maintenance of energy and 0.5, 1 and 1.5 times the requirement of protein. At least 94 per cent. of the cellulose in the diets was provided by the hay, the rest by flaked maize.

The digestibility of cellulose assessed by the method of Norman and Jenkins (*Biochem. J.*, 1933, **27**, 818) was depressed by the addition of maize starch or flaked maize, and the addition of

protein had no effect, either because insufficient was given or the protein used was unsuitable. Increase of the intake of N but not of starch increased retention of N. When starch was added to half maintenance requirement with 2.5 to 3.5 times the protein requirement as maize gluten there was still no effect on N balance or on the digestibility coefficients of cellulose or dry matter, but those of other nutrients decreased. In further tests starch was not given or was given at half maintenance level with 0.5, 1.0 or 1.5 times the requirement of protein as white fishmeal or casein. Digestibility of cellulose and dry matter was unaffected by type or amount of protein; that of nitrogenous material was increased by extra protein, especially fishmeal, and decreased by starch, especially potato starch. Retention of nitrogen increased with increased levels of starch or protein.

When urea was added to the diet in N-equivalent amounts, the digestibility of cellulose, dry matter and other nutrients was unaffected by varying the levels of starch and protein, but protein digestion was improved. N retention was poor with diets containing urea but was improved by 1 g. DL-methionine daily.

The addition of B vitamins to a daily diet of 1100 g. hay did not affect digestibility of dry matter or N, or N retention.

It is suggested that growth of micro-organisms responsible for digesting cellulose in the rumen is not dependent on extra N if the substrate they are digesting contains about 1 per cent. N.

- CARDON, B. P. Influence of a high salt intake on cellulose digestion. *J. Animal Sci.*, 1953, **12**, 536-540. [Dept. Animal Husb., Univ. Arizona.]

Salt at the rate of 1.8 lb. in the ration or 2 lb. as a drench per head daily was given to 3 Hereford cows. The daily ration was 15 lb. alfalfa hay per head. The salt did not affect the digestibility of cellulose, which was about 55 per cent.

Experiments *in vitro* confirmed these findings, and the addition of 3.3 per cent. molar phosphate buffer solution was also without effect on digestibility.—T. D. Bell.

ACCARDI, F. Indagine sul valore nutritivo del trifoglio alessandrino (*Trifolium alexandrinum* L.) in coltura asciutta. [Nutritive value of berseem clover, *Trifolium alexandrinum*, L., in dry culture.] *Zootec. Vet.*, 1953, **8**, 207-216. [Ist. Zootec. Gen., Univ. Palermo.] English and German summaries.

The nutritive value and digestibility of berseem grown in the hot dry climate of Sicily were estimated with 6 mature dairy cows. The clover was the last cut of the season, and 7 samples were analysed, giving the following composition: crude protein 15.75 to 19.68, ether extract 2.64 to 4.13, crude fibre 29.16 to 32.81, N-free extract 39.00 to 43.92, ash 7.22 to 9.92 per cent. of dry matter. The average dry matter was 17.92 per cent. Digestibility coefficients were: crude protein 66.94 to 70.01, ether extract 47.63 to 50.84, crude fibre 49.79 to 52.93, N-free extract 68.29 to 71.43. The nutritive value was 0.52 feed unit per kg. dry matter.—T. D. Bell.

BROZZETTI, P. Il fieno dei prati-pascoli dei Monti Sibillini. Composizione, digeribilità e valore nutritivo. [Hay from the pastures of Monti Sibillini. Composition, digestibility and feeding value.] *Riv. Zootec.*, 1953, **26**, 212-217. [Ist. Zootec. Gen., Univ. Perugia.]

The pastures of the Monti Sibillini are uncultivated and although some hay is made in the early summer they are for the most part intensively grazed by flocks brought on to them for the season. The pastures are very rich and produce excellent meat and milk for cheesemaking. Hay was cured in the field in 5 areas, and a composite sample, considered to be representative, was analysed and used in digestibility trials with 2 rams. The results showed good digestibility, composition and feeding value compared with values reported by other authors for hay from mountain pastures.

DAS, B. K. and MUKHERJEE, N. C. **The nutritive value of the indigenous grasses of Assam. 6. The grass Joy-joha (*Ischaemum rugosum* Salisb.) as a cattle feed.** *Indian J. Vet. Sci.*, 1952, **22**, 239-246. [Animal Nutrit. Res. Scheme, Gauhati.]

Joy-joha was cut at the flowering stage and given as green fodder for 31 days to 4 Assamese bullocks of average weight 570 lb. Excreta were collected during the last 10 days. Dry matter consumption was on the average 1.89 lb. per 100 lb. bodyweight, which showed that the fodder was highly palatable. Digestibility coefficients were: dry matter 58, crude protein 62, ether extract 71, crude fibre 63, N-free extract 59 and total carbohydrates 60. A similar procedure was followed with hay made on the tripod system from the grass cut at the same stage of growth. It was less palatable. Digestibility coefficients were, in the same order: 52, 42, 55, 66, 49 and 56. The results of chemical analyses are presented in detail. At the flowering stage the green fodder contained 7.13 per cent.

N.A. and R., January 1954

crude protein on a dry matter basis. Digestible protein and starch equivalent were, respectively, 1.25 and 10.88 lb. per 100 lb. fresh matter. The hay contained 6.63 per cent. crude protein on a dry matter basis and the digestible protein and starch equivalent were, respectively, 2.4 and 26.7 lb. per 100 lb. hay.

The animals showed positive balances of Ca and P when given the green fodder. With hay a positive Ca balance was not always found, but P was adequate.—P. C. Jowsey.

ROBERTS, L. P. **Bact. coli as a food supplement.** *Nature*, 1953, 172, 351–352. [Evans Biol. Inst., Runcorn, Cheshire.]

A strain of *Bacterium coli* from a collection of calf scour strains was cultured in a synthetic medium containing ammonia and glucose; 100 litres yielded about 400 g. bacterial protein ($N \times 6.25$).

When groups of young rats fed to appetite on a basal diet with 11.5 per cent. protein, consisting of barleymeal 2 parts, bran 1 part, with 0.5 per cent. cod liver oil, were given supplements of 5 per cent. *Bact. coli* protein or 5 per cent. fishmeal protein, the increases in weight gains were equal and significant.

When chickens on a basal ration with 11.9 per cent. protein, consisting of barleymeal, bran, 2 per cent. grassmeal and 0.5 per cent. cod liver oil were given supplements of bacterial protein or fish solubles, growth rate was grossly subnormal, but with both 5 per cent. bacterial protein and 1 per cent. fish solubles, growth rate in the first 4 weeks of life was significantly better than that of controls given fishmeal plus fish solubles and equal to that of controls on a commercial chick mash. The optimum percentage of bacterial protein is not known but is thought to be considerably below 5 per cent. but greater than 1 per cent.

The economic possibilities are indicated and it is suggested that *Bact. coli* protein might be used in the rations of other farm animals.

W. M. Deans.

1252

ROBERTS, R. S. **The use of bacteria as a food supplement.** *Vet. Rec.*, 1953, 65, 573. [Evans Biol. Inst., Runcorn, Cheshire.]

In experiments similar to the above, rats given a supplement of 1.0 to 1.56 per cent. "coliform protein" showed growth equal to that of controls given rat cubes prepared according to the formula of the Medical Research Council.

Baby pigs were given the basal diet used for chicks with 2 per cent. coliform protein added and gained on the average 7.2 lb. in 14 days. On the basal diet alone the average gain was 5.2 lb.; the difference was statistically significant.

- HANSSON, A. **Samspelet mellan arv och uppfödningens intensitet när det gäller nötkreaturens tillväxt, mjölkavkastning och livslängd. [The interaction between heredity and plane of nutrition during rearing with reference to the growth, milk yield and life span of cows.]** *Kgl. Lantbruksakad. Tidskr.*, 1953, **92**, 85-98. English summary.

Three preliminary experiments are briefly sketched, which were designed to investigate the effect of plane of nutrition during early growth on the variables listed. These experiments showed that plane of nutrition affected chiefly the speed of growth. From this result it is deduced that longevity should be found with a low-plane rather than a high-plane system. Intensive feeding appeared to have little effect on milk yield. As a consequence of these experiments, which also suggested that heredity had a considerable effect on these variables, a more detailed study, using 16 pairs of identical twins, was made.

The design of this experiment is described in detail. One twin of each pair was fed on a standard according to its age and growth capacity. The pairs were divided into 4 groups of 4 and the other twin of each pair (the experimental animal) was allowed 60, 80, 120 or 140 per cent. of the control twin's diet up to 25 months of age, and after that the same diet as the control. The feed intake was averaged monthly, as was the body-weight, and graphs and tables give the feed intake and growth over chosen periods, as well as growth per feed unit eaten. The first conclusions to be made are drawn from Fig. 3. These are that the young animal has a high growth capacity, so that the rate of growth can be influenced by feeding. If in any early age interval the animal is given plenty of food and grows well, then in the next interval the capacity for growth will be reduced. From this and previous experiments it is suggested that, within the limits of plane of nutrition in this experiment, heredity and not intensity of feeding determines the bodily development at maturity.

Growth was divided into 3-monthly periods and an analysis of variance made on log growth. This was used to confirm the results above. Again the author reasons that "growth passes without detectable break into senescence", implying that the length of life is to a great extent influenced by the supply of food. "We have therefore shown that a low plane of nutrition delays development and increases length of life in as widely separated

organisms as uni-cellular organisms, insects, frogs, fishes, mice and rats." The conclusions on length of life in cows, as far as can be decided from the paper, are based on a selected sample.

In the next stage of the study the growth per feed unit was investigated. It is shown clearly that growth per feed unit decreases with age, in a similar fashion for the different planes of nutrition. Fig. 5 shows the growth in g. per feed unit averaged over the 24-month experimental period plotted against plane of nutrition. There is a negative linear relation, from which it is reasoned that utilisation of feed depends on the plane of nutrition. In an attempt to explain this relation, a digestibility trial was made from 21 to 24 months of age. Table 5 shows similar digestibility coefficients in all groups, leading to the reiteration that the utilisation of digested feed must be affected by plane of nutrition. An analysis of variance is carried out similar to that on log growth, and is used to support the conclusions above. [Between experimental groups *P* should be 0.05, and also 0.05 between twin pairs (heredity).]

Frequency of respiration and heart rate were recorded for half the animals from the 10th to the 25th month and the figures given showed both variables to increase as the plane of nutrition rose.

Milk yield was next investigated, and it was concluded that a certain negative relation exists between the plane of nutrition and the future milk yield. The author here inserts a caveat concerning the extent of the data, obtained from 30 first or second lactations, and because the rations of the high-plane cows had been abruptly reduced to those of the controls.—A. W. Boyne.

DAHMEN, J. J. and BOGART, R. **Some factors affecting rate and economy of gains in beef cattle.** *Oregon Agric. Exp. Stat. Tech. Bull.* No. 26, July 1952, pp. 23. [Corvallis, Oreg.]

Seventy-four individually-fed beef calves were studied in 2 groups. One group of 25 purebred Hereford and Angus calves of both sexes were born during the first half of 1949 and were fed over the following winter and spring. The second group, consisting partly of purebred Hereford and Angus bulls and heifers and partly of grade Hereford steers and heifers, were born during the 1950 spring and summer and were fed over the following winter and spring. The results showed that bulls were much more efficient feed converters than heifers, and also made an average daily liveweight gain of 2.3 lb. compared with 2.0 lb. for heifers. The age at slaughter was found to be significantly related to birthweight; the higher the birthweight the sooner the animal reached slaughter weight, but no relation was found between suckling gains and gains in the feed lot.—E. L. B. Haskew.

HIBBS, J. W., POUNDEN, W. D. and CONRAD, H. R. **A high roughage system for raising calves based on the early development of rumen function. 1. Effect of variations in the ration on growth, feed consumption, and utilization.** *J. Dairy Sci.*, 1953, **36**, 717-727. [Ohio Agric. Exp. Stat., Wooster.]

Jersey and Holstein calves were used in 2 experiments to find the effect on cost and efficiency of feed utilisation of varying a basic high-roughage ration.

In the first experiment a simple grain concentrate mixture containing 14.5 per cent. total protein was compared with a complex mixture containing 25 per cent. total protein. In both rations the ratio of hay to grain was 2 : 1. In the second experiment the effect of giving whole milk for 7 to 9 weeks with or without a vitamin B₁₂ supplement and using a 4 : 1 hay : grain ratio was studied. The performance of calves given the 2 : 1 and 4 : 1 hay : grain ratios was also compared. In both experiments the calves were inoculated with fresh cud taken from older cattle.

Under the conditions of these experiments there was no difference in growth between calves given simple and complex grain mixtures. Efficiency of feed utilisation was affected by the kind of hay; calves given high quality alfalfa hay gained more efficiently and at lower cost than calves given a mixture of alfalfa and timothy hay. The calves on the 2 : 1 hay : grain ratio had a higher efficiency of feed utilisation than those on the 4 : 1 ratio. There was no advantage in giving a vitamin B₁₂ supplement.—J. N. Aitken.

ROLLINSON, D. H. L. A comparison of the effects of phenothiazine dosage with and without a mineral lick supplement on indigenous calves in Uganda. *J. Comp. Pathol.*, 1953, **63**, 159-170. [Animal Health Res. Centre, Entebbe, Uganda.]

Over a 34-week period groups each of 7 grazing calves were given phenothiazine monthly, phenothiazine monthly and a mineral lick, or a mineral lick, or were untreated. Growth was not significantly improved by phenothiazine alone but was by phenothiazine and minerals and, to a less extent, by minerals alone. Worm egg counts were highest in the mineral group and significantly lowest in both phenothiazine groups, the controls being intermediate. There was little group difference in blood inorganic P estimated on 3 occasions, though the mineral group mean was highest each time and the phenothiazine group lowest. Compared with controls the minerals-only group was significantly lower in Hb and cell volume and the phenothiazine group significantly lower in Hb only.—W. Thomson.

KAJANOJA, P. Über die Einwirkung der Unterernährung auf die Milchproduktion der frischmelkenden Kühe. [Effect of underfeeding on milk production of cows in early lactation.] *Acta agral. fenn.*, 1944, 56, No. 3, pp. 132.

The experiments reported in detail here were made during the years 1936 to 1938 and 1940 to 1941. Newly calved cows were placed on experiment from the day of calving. The rationing was by one of two plans. In the first, the cows were given a ration providing an energy intake considerably lower than that necessary to supply the requirement for the expected yield of the cow. After the yield of milk had become stable, the energy intake was increased gradually until it supplied an amount adequate for the expected milk yield. In the second, the cows started on an adequate ration, then, in a second period, had the energy intake considerably reduced and in a third period had it restored. Similar trials in which the protein intake was altered and the energy intake kept adequate were made with other cows. The length of all periods had to be short, 2 to 3 weeks, and in order to allow for this and for individual variation between cows with respect to feed requirements and utilisation, 27 cows were used in the energy intake trials and 24 in the protein intake trials. The results are submitted in detail, and the following is a brief summary of the findings.

A cow receiving less energy in its ration than that required for its milk-producing capacity gives a low yield, which, however, is higher than that calculated from the energy intake; the balance of the energy it takes from its body fat reserves. Thus in the first experiments the average daily milking capacity of the cows was 18.16 kg. daily and the energy intake was adequate only for 13.83 kg. The average actual yield was 16.44 kg. The cows therefore produced on the average 2.61 kg. from their body reserves, the total milk yield falling below capacity by only 1.72 kg. The milk produced at the expense of body fat was equivalent to about 65 per cent. of the deficiency of energy intake. With greater feed deficiency both the milk produced at the expense of body fat and the difference between expected and actual yield increased, but a smaller percentage of the latter deficiency was made up at the expense of body fat. When the feed (energy) supply to an undernourished cow was increased, the effect on milk yield was seen within 4 to 5 days. Its effect,

depending upon the intake, was (1) to increase milk yield, (2) to limit production of milk at the cost of body fat or (3) to increase body fat. This third effect came into force only if the extra intake was more than adequate to meet the requirements for (1) and (2). In some cases the milk produced at the expense of body fat reached considerable amounts. Thus with 6 cows on inadequate energy intake 6 kg. milk daily or 400 kg. in all were produced during an experimental period of several weeks. These and other results in the literature suggest that milk production at the expense of body fat may amount to 10 to 20 kg. daily or a total of 600 to 900 kg. On the other hand, temporary undernourishment for short periods (up to 2 weeks) may not affect total milk yield to any appreciable extent over a whole lactation. Undernourishment of newly calved cows may cause a rise in the percentage of fat in the milk, but has no appreciable effect on its protein content.

With newly calved cows it would appear that the protein supply can be materially lower than the standards generally recommended without the lack of protein acting as a limiting factor in milk production. If the quantity of digestible pure protein for maintenance is estimated at 75 g. for each feed unit (Scandinavian) necessary for maintenance and if 30 to 40 g. is provided for each kg. milk there is no certain reduction of milk production. If the production protein supply falls below 30 g. per kg. milk, then milk yield may fall by 0.5 to 1 kg. daily. A very low protein intake reduces the fat content of the milk, but has no perceptible influence on the protein content. After a period of very low protein feeding the effect of extra protein intake on the milk yield becomes noticeable in about 6 days.

The findings reported are in accord with those reported by other workers. In such experiments where the protein intake was only equivalent to that required for maintenance and 1.2 to 1.3 times the amount present in the milk, yield was normal over long periods, sometimes the whole lactation, and the cows remained in normal health. Protein supplied in more than standard allowances did not increase milk yield; abundant excess tended to reduce it.—W. Godden.

FINSTAD, K. Beitet på Apelsvoll. [The Apelsvoll pastures.] *Tidsskr. norske Landbruk*, 1953, 60, 53-81.

A detailed account is given of the management and use of pasture at this research station from 1946 to 1950. Fertiliser was increased experimentally up to a maximum above which the computed yield of feed units per unit area could not be raised. At the maximum, the milk cows on

the heavily fertilised area were producing 50 per cent. more milk over the year, per unit area, than the average for the whole area.—I. Leitch.

HEWITT, A. C. T. **Dairy cattle feeding trials. Concentrates v. no concentrates.** *J. Dept. Agric., Victoria*, 1953, **51**, 193–200; 229–232.

Feeding trials were made over 3 years on 3 farms in each of 4 areas of Victoria. One of these areas is dealt with in some detail. The farms were all devoted to pasture for milk production. On each farm no concentrates were given in one year, high-protein concentrates at the rate of about 1000 lb. per cow per year in another, and low-protein concentrates at the same rate in the third. The use of concentrates increased the yield of milk and butterfat, but the cost far exceeded the returns from the increased production. The treatments did not affect the health of the animals, which was at all times good.—T. D. Bell.

CABRERA, J. I. and RIVERA-BRENES, L. **The value of grass silage for feeding dairy cows in Puerto Rico.** *J. Agric. Univ. Puerto Rico*, 1953, **37**, 59–73. [Dept. Animal Husb., Agric. Exp. Stat., Univ. Puerto Rico, Rio Piedras.] Spanish summary.

A series of trials were made to compare the value of different silages and freshly cut grasses for milk production. The grasses used were Merker grass (*Pennisetum purpurascens*, var. Merkerii) at early and mature stages, and Para grass (*Panicum purpurascens*) ensiled with 5 or 10 per cent. molasses, and ensiled whole immature sugar cane. The trials extended over 3 years, and milk production was recorded for comparable groups of cows receiving concentrates at the rate of 4 lb. per gallon. Proximate analysis of the roughages are reported.

Silages were superior to freshly cut grass, except for Para grass silage with 5 or 10 per cent. molasses, which was not so good as freshly cut mature Merker grass. Merker-kudzu silage was only equal to freshly cut Merker grass. Sugar cane silage was excellent.—T. D. Bell.

SMITH, S. E., LENGEMANN, F. W. and REID, J. T. **Block vs. loose salt consumption by dairy cattle.** *J. Dairy Sci.*, 1953, **36**, 762–765. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

The consumption of salt in loose or block form by lactating cows grazing 3 types of pasture was measured. In 2 out of 3 summer seasons the cows consumed more loose than block salt. Salt consumption was greater on Kentucky bluegrass and white clover pasture than on ladino clover and orchard grass or alfalfa, ladino clover and brome-grass.—J. N. Aitken.

Regulations for the feeding of cows producing milk for children have been in force in Denmark

N.A. and R., January 1954

since about 1880. They arose from hypothetical reasoning about the poor quality of milk produced by the early co-operative dairies. *Cruciferae* might not be used; not more than 30 kg. roots of the beet family might be given daily; residues such as brewer's and distiller's grains, sugar beet pulp, molasses and mustard seed and rapeseed cakes were forbidden; only 0.5 kg. cottonseed cake daily might be used. These regulations were modified in 1937 and again in 1941 in respect of the use of roots, but the total embargo on brewer's grains and rapeseed and mustard seed cakes remained. The use of silage was restricted. The experiments described here were planned in relation to these decisions.

The experiments were made during 4 winters, 1943 to 1944, 1944 to 1945, 1946 to 1947 and 1949 to 1950. The milk, test and control, was produced by 2 groups of cows on the same farm and distributed from the same dairy to the children's homes.

The first test was concerned with brewer's grains and root top silage. There were 28 cows of average age 5.5 years and 5 months in milk. All had 4 feed units of fodder beet, 2 kg. hay, 4 kg. barley straw and 1 kg. mustard seed cake. Those that gave more than 6 kg. of 4 per cent. milk were given also for each 2.5 kg. of 4 per cent. milk over 6 kg., 1.1 kg. of a mixture of 10 parts mustard seed cake, 10 linseed cake, 5 meat-and-bone meal, 20 ground barley, 25 ground oats and 30 malt sprouts. The test cows had 7.5 kg. brewer's grains instead of 1.65 kg. of that concentrate mixture. This continued from December to April. From 5 April to 30 April the test cows, with 3 replacements, had silage instead of brewer's grains.

There was no difference in bacteriological findings between the groups. On the average the experimental cows produced slightly less dry matter and fat in milk. There was no great difference in vitamin A or carotene content; the silage milk had a little more carotene.

There were 70 control and 87 test children in 6 homes. There was no difference in rate of growth or health as judged by the incidence of normal and abnormal stools.

Two further experiments on the same pattern were concerned with root top silage, and the last with grass silage. The ration with grass silage gave more milk with more vitamin A and carotene than the control. There was no difference between the groups of children in any of the tests.

THOMAS, J. W. and MOORE, L. A. **Thyroprotein feeding to dairy cows during successive lactations.** *J. Dairy Sci.*, 1953, **36**, 657-672. [Bur. Dairy Indust., U.S. Dept. Agric., Washington, D.C.]

Thyroprotein was given to a group of 20 lactating Holstein and Jersey heifers at the rate of 1.0 or 1.5 g. per hundredweight [? 100 lb.]. Treatment was continued during successive lactations from the 50th day after calving until 90 days before the next expected calving. On the average treatment lasted for about 300 days. Fifteen of the cows completed 2 lactations, 9 completed 3, 4 remained in the herd through 5 and 3 completed 6 lactations. In a control group of 8, 6 cows completed 2 lactations, 5 completed 3, 2 completed 5 and 1 completed 6. During the first lactation 9 treated and 4 control cows received a total digestible nutrient (T.D.N.) intake equal to requirement. The remaining cows in both groups were given T.D.N. at 125 per cent. of requirement. In subsequent lactations all cows were given 125 per cent. of requirement whenever thyroprotein was given. Feed consumption and yields of milk and butterfat were recorded.

There was an immediate increase in yield of milk and butterfat production when thyroprotein was given. The increases were sustained over a longer period when the extra nutrients were given. The total milk yield of the treated cows over any one lactation was not greater than that

of comparable control cows. Cows given thyroprotein lost weight during treatment, but regained it rapidly when thyroprotein was stopped. The feed conversion efficiency of the treated group decreased with each succeeding lactation. Mortality was high among calves from the treated cows.

It was concluded that thyroprotein for long periods during lactation is not desirable.

REPRODUCTION

1304

RIGGS, J. K., COLBY, R. W. and SELLS, L. V. **The effect of self-feeding salt-cottonseed meal mixtures to beef cows.** *J. Animal Sci.*, 1953, **12**, 379-393. [Dept. Animal Husb., Texas Agric. Exp. Stat.]

In 1949 to 1950, 35 in-calf Angus, Hereford and Shorthorn cows were divided into 2 groups and wintered on 200 acres of unimproved upland pasture. One group was hand-fed with 2 lb. cottonseed meal per head daily, the other group had free access to a mixture of 15 to 35 per cent.

common salt and 85 to 65 per cent. cottonseed meal. Four groups of 5 in-calf beef cows of mixed breed were wintered over 1950 to 1951, one group with hay and cottonseed to appetite, the other 3 self-fed with cottonseed meal salted enough to limit the intake to about 2 lb. per head daily. A sub-maintenance ration of hay was given to one of these groups, a maintenance ration to another and hay to appetite to the third. Results indicate that a high salt intake had a beneficial effect upon digestibility of all the nutrients, but the use of salt limited the consumption of concentrates accessible to appetite. Provided water was always available and the salt was introduced gradually, a high salt intake appeared to cause no damage to the kidneys, nor to have any detrimental effect on the health or reproductive ability of the cows.—E. L. B. Haskew.

1305

MANN, T. and WALTON, A. **The effect of under-feeding on the genital functions of a bull.** *J. Agric. Sci.*, 1953, **43**, 343-347. [Molteno Inst., Univ. Cambridge.]

After a 5-week preliminary period on a normal ration, a 5-year-old Dexter bull was kept for 23 weeks on a ration which was at first half the normal, and later reduced to starvation level (15 lb. barley straw daily). During this period it lost weight rapidly. It was then returned to the normal ration for 25 weeks and regained weight. The reduced ration did not affect volume or density of semen, or motility or morphology of spermatozoa. The secretory function of the accessory glands was affected; the citric acid and fructose contents of the semen were much reduced, but gradually returned to normal during the recovery period.—T. D. Bell.

SHEEP

1306

THOMSON, W. and THOMSON, A. M. **Effect of diet on milk yield of the ewe and growth of her lamb.** *Brit. J. Nutrition*, 1953, **7**, 263-274. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Ewes from a previous experiment (Abst. 2922, Vol. 19), which had been maintained during late pregnancy on high- or low-plane diets, and their lambs, were used. High-plane ewes suckled their own lambs or lambs from low-plane ewes, and low-plane ewes suckled their own or lambs from high-plane ewes. After lambing the ewes all received adequate rations of concentrates, hay and swedes or grass, and lambs had access to concentrates, hay and grass as soon as they would eat them.

The milk yield of the high-plane ewes was about 20 gal. in 13 weeks' lactation, compared with 11

gal. for the low-plane ewes, and the increase in the feed of the latter after lambing did not increase the milk supply quickly enough to be of full benefit to the lambs. In the low-plane ewes udder development was severely retarded, particularly in those bearing twins, and this was reflected in the milk supply and weight increase of the lambs. Lambs transferred to high-plane fostermothers from low-plane mothers benefited from the greater milk supply, though at weaning they had not caught up with those from high-plane mothers. There was a high mortality rate among those transferred from high-plane ewes to low-plane.

It is concluded that undernutrition in late pregnancy greatly affects the size and vitality of the lamb and the milk yield of the ewe, particularly in early lactation.—T. D. Bell.

- GARRIGUS, U. S., KAMMLADE, W. G., BOLEY, L. E. and HARDENBROOK, H. (Jr.) **A study of elemental sulfur and of some other suggested preventives of enterotoxaemia in a lamb fattening ration.** *J. Animal Sci.*, 1953, **12**, 474-479. [Dept. Animal Sci., Coll. Agric., Univ. Illinois.]

Two series of trials with Western feeder lambs, each lasting for 84 days, are reported. In the first series elemental S did not reduce the efficiency of feed conversion or eliminate losses from enterotoxaemia when added, at the rate of 1 to 2 per cent. of the maize allowance, to a ration of maize, maize silage, soya bean meal and powdered limestone. In the second series, the mean daily weight increment was 0.33 lb. for lambs receiving 1/3 oz. S daily, compared with 0.29 lb. for untreated controls, when both groups daily received 3.7 lb. maize silage, 1.2 lb. corn-and-cob meal, 0.216 lb. soya bean meal, 0.027 lb. iodised salt and 0.027 lb. powdered limestone. The addition of extra cobs to the corn-and-cob meal or of 0.112 oz. NaHCO_3 daily did not influence the rate of gain of other groups in the second series.

- GORB, T. V. and GRISHPAK, V. F. **O kormlenii i soderzhanii karakul'skikh matok na Ukraine. [Feeding and care of karakul ewes in the Ukraine.]** *Karakul. Zverovodstvo*, 1953, **6**, No. 1, 26-33. [Ukrainsk. N.-I. Inst. Zhiot.]

Nutrition tests during different periods of pregnancy were made as follows. Of 4 groups of 53 ewes each, the first and fourth were given regular rations, the first being fed plentifully, the fourth moderately. The second group was fed plentifully for 3 months and then moderately, the third group vice versa. The third group produced the largest number of lambs with good fleeces. The following rations are recommended for pregnant ewes: during the first period 1.5 kg. hay and 0.1 kg. concentrates; during the last 2 months the ration should be increased gradually to 2 kg. hay and 0.2 kg. concentrates. Hay should be

Vol. 24, No. 1

given 4 times a day, and 0.3 to 0.5 kg. succulent fodder (beetroot) improves the condition of the animals.—E. W. Birse.

- SLEN, S. B., WHITING, F., PETERS, H. F. and MACNAUGHTON, W. N. **A comparison of certain breeds of range sheep under different environmental conditions.** *Canad. J. Agric. Sci.*, 1953, **33**, 344-353. [Exp. Stat., Lethbridge, Alta.]

The wool and lamb production of 50 Canadian Corriedales and 50 Romnelets (Romney \times Rambouillet) were compared over 3 years on one station and with those of similar groups on a second station 200 miles away, where a group of 50 Rambouillets was included in the study. Highly significant wool differences between stations suggested that environment, including plane of nutrition, was of greater importance than breed differences. The Rambouillet yielded significantly more wool than the other breeds, which did not differ in this respect. Canadian Corriedale lambs were significantly heavier at birth than Romnelet lambs, but at weaning there was no difference. Station differences were significant at weaning only. On a fattening ration daily gain, feed conversion efficiency and dressing percentage were similar for all breeds. Rambouillet carcass grade was inferior to that of the other breeds.

1314

- SHELTON, M., HARDY, W. T., WARWICK, B. L., MILLER, J. C. and PATTERSON, R. E. **Skin folds in Rambouillet sheep.** *J. Animal Sci.*, 1953, **12**, 440-450. [Texas Agric. Exp. Stat., Substat. 14, Sonora.]

In a flock of about 200 ewes, divided into 2 groups on the basis of the number of skin folds, the smooth group yielded slightly less grease wool

than the folded, but were superior in staple length and clean wool, and were heavier at weaning and as yearlings. Rams with folded skins had shorter staple length and greater weight of grease wool and bodyweight than smooth rams. The number of skinfolds increased with age.

The ewes were range-fed, and records for 6 years were considered. Variation between years was significant; this was thought to be due to changes in the plane of nutrition. The greater

number of skinfolds in rams compared with ewes was also thought to be due to nutrition, since they were fed better than the ewes on range. In both sexes conformation scores were higher for the smooth types. On the whole the advantages of the smooth types outweighed the slight advantage of the folded in yield of grease wool, and the former should be encouraged in breeding projects.

PIGS

1315

DYRENDALH, S., SWAHN, O., BJÖRCK, G. and HELLVING, L. **Artificial raising of baby pigs.** *Acta Agric. scand.*, 1953, **3**, 334-354. [Royal Vet. Coll., Stockholm, Sweden.]

The artificial rearing of 52 normal piglets and 40 from dams unable to suckle them is reported. The metal and wooden types of brooders used, with the necessary heating and feeding arrangements, are described. The piglets were put in the brooders at 2 to 3 days of age and transferred to heated pens after 3 weeks. They were fed on a commercial synthetic milk, "Grix", and a commercial pig starter meal, "Trind", the compositions of which are given.

The piglets gained well, and at 56 days weighed 19.6 and 14.4 kg. for normal and "catastrophic" litters, respectively. Feed consumption was 2.5 Scandinavian feed units per kg. liveweight increase.

Essential features for artificial rearing are supply of a palatable milk substitute, heated draught-proof brooders, scrupulous cleanliness and a high-protein meal from 10 to 20 kg. liveweight. The economic aspect of artificial rearing is discussed.—T. D. Bell.

1316

TEBBUTT, N. F. **Rearing orphan piglets with a foster-mother.** *Vet. Rec.*, 1953, **65**, 416. [Oundle.]

The successful rearing of 8 piglets whose dam died immediately after parturition is reported. The piglets were bottle fed for the first day, and then fed from an Arnold stone jar fostermother till the 25th day. The fostermother and teats must be kept absolutely clean by scalding, and the teat holes may have to be enlarged. The milk mixture given is described. After the 25th day it was given in a trough. Since meal consumption was still low at 35 days, the milk was then given after the meal. At 8 weeks the piglets were eating 2 lb. meal and 4 pints of milk mixture; the latter was then gradually discontinued. There was no scouring until the 21st day, and this was quickly controlled. After the addition of penicillin to the

meal, on the 25th day, the piglets made great progress, and at 8 weeks compared favourably with those reared on the same farm in the normal way. The extra labour seemed economically justifiable.—T. D. Bell.

1317

SEWELL, R. F., SHEFFY, B. E., EGGERT, R. G. and LOOSLI, J. K. **Studies on the protein requirement of suckling pigs.** *J. Animal Sci.*, 1953, **12**, 597-604. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

In 4 trials with suckling pigs taken from their dams after 2 days, the growth rates for 1 month of groups receiving synthetic milk diets containing 16, 20, 24, 28 and 32 per cent. protein on an air-dry basis were compared. Isolated soya bean protein was used in 2 trials, and casein in the others. The higher the protein content, the greater the growth rate and efficiency of feed utilisation. Casein was slightly better than soya protein in promoting growth.

Pigs from the last trial were kept on an adequate ration for a further 3 weeks. The rates of gain were affected by the previous treatment, the pigs on the lower protein levels growing more slowly. The nutritive ratios of the diets, in ascending order of protein content, were: 1:6.5, 1:5.1, 1:4.0, 1:3.3 and 1:2.9. Normal sow's milk has a nutritive ratio of 1:3 or 4, and a protein content of from 29 to 34 per cent.—T. D. Bell.

DINUSON, W. E., KLOSTERMAN, E. W., LASLEY, E. L. and BUCHANAN, M. L. **Cobalt, alfalfa and meat scraps in drylot rations for growing-fattening pigs.** *J. Animal Sci.*, 1953, **12**, 623-627. [N. Dakota Agric. Coll., Fargo.]

N.A. and R., January 1954

Four rations were given: a maize and soya bean meal ration alone or with meat scraps or dried alfalfa, or both. Each ration was given alone or with one of the following supplements: cobalt, vitamin B₁₂, cobalt plus vitamin B₁₂, a commercial trace mineral mixture. In all 120 Duroc pigs of average initial weight 54 lb. were used and kept on concrete floors until they reached about 200 lb. liveweight. The results are presented in detail and analysed statistically.

Cobalt increased the rate of gain significantly on all rations and meat scraps increased the rate of gain over that on maize and soya bean meal alone, the increase being greatest with pigs which received cobalt also. Dried alfalfa significantly decreased the rate of gain, irrespective of the supplement.—P. C. Jowsey.

VAN WYK, H. P. D. and VERBEEK, W. A. **Feeding methods to supply protein requirements of growing pigs.** *Farming in S. Africa*, 1953, **28**, 155-156; 158. [Coll. Agric., Potchefstroom.]

An experiment was made to find a practical method of reducing the consumption of protein-rich concentrates by fattening pigs after the period of rapid growth. Large White pigs were fed from 50 to 200 lb. liveweight on yellow maize meal and a protein-rich concentrate of white fishmeal, wheat bran, groundnut cake and alfalfa meal. One group received a mixture of 70 per cent. maize and 30 per cent. protein concentrate, starting with 2 lb. and finishing with 7 lb. per head daily. The other group had 1 lb. protein concentrate daily, the weight of total feed being made up with maize. The groups gained weight (1.50 and 1.54 lb. daily) and graded equally. The carcasses of the restricted pigs had slightly more fat than the others, but not sufficient to affect grading. Both groups were equally efficient in feed conversion (3.16 and 3.15 lb. feed per lb. liveweight increase). The protein provided by the limited ration was adequate, that by the other was excessive, and the difference in protein concentrates used was considerable, 67 lb. as compared with 95 lb. per 100 lb. liveweight increase.—T. D. Bell.

VAN ALBADA, M., UBBELS, P., DAMMERS, J. and FRENS, A. M. **Proefnemingen met varkens en kuikens over de bruikbaarheid van enige producten ter besparing van dierlijke eiwitten (vismee, diersme, enz.) bij de veevoeding. Tweede serie 1951. [Tests with pigs and chicks of the suitability of some products to save animal protein (fishmeal, meatmeal, etc.) in stock feeding. Second series, 1951.]** *Versl. Landbouwk. Onderzoek.*, 1952, No. 58-8, pp. 126. English summary.

Vol. 24, No. 1

The first 35 pages of this report are devoted to a review of the literature. The trials are a continuation of work already reported (Abst. 1404, Vol. 22). The general plan of the experiments was: a group with the normal amount of animal protein (positive control); one with about one-quarter of that amount of animal protein (negative control); one or more given the test product in addition to protein as in the negative control or occasionally in the normal ration. With the chickens there were sometimes also groups with half normal animal protein or groups with little or none. The positive controls had Dutch freshwater fishmeal or Norwegian herring meal.

The products tested were: whale solubles; U.S. Industrial Chemicals vitamin B₁₂ concentrate, 12 mg. per kg., high in protein and B complex generally; a vitamin B₁₂ product of the Centrale Suiker Maatsch., Amsterdam, containing 5 mg. per kg.; Eiwitkern-Trouw, also an Amsterdam product, a soya bean meal, processed and with vitamin B₁₂ added, 0.9 mg. per kg.; Grastell condensed fish solubles, an English product; Norwegian condensed fish solubles.

The pig trials were made independently at 5 centres, with in all 200 young pigs, from an initial weight of 15 to 20 kg. to a slaughter weight of 55 to 60 kg. The results are described in detail and set forth in 10 tables including the statistical summary with English and Dutch legends.

The meal mixtures used were more complex than those used in 1950 and more attention was paid to the amino-acids supplied, so that there was less difference than in 1950 in respect of methionine and lysine between positive and negative controls. The importance of the nutritional history of the pigs was obvious. Two centres had to buy in some pigs for the experiments and only there was there a significant difference between positive and negative controls. Dutch freshwater fishmeal was as good as Norwegian herring meal, and there was no advantage in adding fish press juice to a normal ration where any important difference between positive and negative controls existed. Vitamin B₁₂ alone could not replace the absent protein.

The chick trials were at 6 centres with 85 pens and 4475 chicks in all. Again the results are set out in detail for each centre separately and summarised. Twelve preparations, vitamin B₁₂ concentrates, fish or whale concentrates or whey products, were tested. The differences produced were small and of little or no practical importance. All market samples of fish solubles were not of equal value. Norwegian condensed fish solubles improved a ration with Dutch fishmeal or Norwegian herring meal; the American vitamin B₁₂ concentrate improved herring meal only. It is suggested that, if attention is paid to amino-acids

in the basal ration and the feeding technique is good, special supplements to "save" animal protein are not required by chicks.—I. Leitch.

POIJÄRVI, I. Beiträge zur Verdauung und Verwertung von Holzzellulose beim Schwein. [Digestion and utilisation of wood cellulose by pigs.] *Acta agral. fenn.*, 1944, **57**, No. 1, 1-53. Finnish summary.

Digestibility trials with adult pigs in which different wood celluloses were used showed wide differences in the results obtained from individual pigs and also in those obtained with the different cellulose preparations. On an average the pigs digested 40 to 50 per cent. of the organic matter of celluloses prepared by the sulphite process. Celluloses from alder or birch woods gave digestibility coefficients of 70 to 80 per cent. and even more; values of 71 to 97 per cent. were obtained for a sulphite cellulose from aspen wood. Fineness of grinding did not appear to affect digestibility but strong chlorination and sometimes mild acid hydrolysis appeared to reduce the digestibility of the cellulose organic matter.

Feeding experiments with young pigs, in which cellulose replaced a portion of the oatmeal in the rations, showed that the use of cellulose, the organic matter of which was digestible to the extent of 85 per cent. by adult pigs, was not profitable in feeding growing pigs. The cellulose could be used as part of the ration for sows non-pregnant or in the early weeks of pregnancy.—W. Godden.

AGRICULTURAL RESEARCH COUNCIL. **Antibiotics in pig food.** *Agric. Res. Council. Rep. Ser. No.* 13, 1953, pp. 20, H.M.S.O., London. Price 1s. 6d. net.

This bulletin reports the results from 19 experiments on the value of aureomycin and procaine penicillin in rations for pigs. The experiments were made at 7 centres and on a number of farms in England and Wales and were co-ordinated by the Agricultural Research Council.

The experiment on creep feeds for suckling pigs covered 208 litters on 13 farms. Aureomycin was included at rates of 28.8 and 43.2 g. per ton of meal and procaine penicillin at 7.5 and 15.0 g. per ton. The differences between weaning weights at 9 weeks were not statistically significant but the results favoured antibiotic supplementation.

In the experiments on pigs from weaning to

bacon weight some rations contained vegetable protein only and others contained both vegetable and animal protein. Supplements of aureomycin (in Aurofac 2A) or procaine penicillin were added. Both the compositions of the rations and the rates of inclusion of antibiotics varied between different experiments. At one centre the pigs were fed to appetite but in all other experiments a feeding scale based on liveweight was used.

Pigs on rations containing animal protein grew 10.3 per cent. faster than the controls if procaine penicillin was included, and 9.4 per cent. faster with aureomycin. Pigs on rations containing vegetable protein only grew 12.4 per cent. faster than the controls if procaine penicillin was included and 16.2 per cent. faster with aureomycin.

The efficiency of feed utilisation was improved by both antibiotics. For vegetable protein rations it increased by 8.2 per cent. with aureomycin and 4.9 per cent. with procaine penicillin; for animal protein rations the respective increases were 6.2 and 7.3 per cent.—I. Lucas.

1325

FERRARI, E. Il rendimento dei suini nella trasformazione degli alimenti in carne e grasso. [Efficiency of pigs in the conversion of feeds to flesh and fat.] *Riv. Zootec.*, 1953, **26**, 224.

In an experiment with 4 groups of about 20 pigs each, starting at 53, 68, 83 and 104 kg. liveweight and fattened in 84 days to 97, 116, 139 and 155 kg., respectively, the feed requirements were 4.76, 4.90, 5.37 and 5.88 feed units per kg. increase. The increase in the heavier pigs was chiefly fat, and the energy value of 1 kg. liveweight increase was 4700 Cal. in the heaviest group, and 4200, 3600 and 3100 Cal. in the other groups, in descending order of liveweight; thus the "physiological return" of the heavier pigs was better. Since the price per kg. of lean and fat pigs is the same, the "economic return" is a different matter, and it is suggested that some adjustment should be made in the marketing system.—T. D. Bell.

1326

HUTCHINSON, K. J. **The influence of feeding practice on baconer carcass quality.** *Queensland Agric. J.*, 1953, **77**, 37-43.

Overfat bacon carcasses, often encountered in the market, should be eliminated by a long-term policy of selective breeding for later maturity. Meanwhile they can be avoided by restricting feeding and consequently rate of growth, in the later stages (100 to 200 lb.) of fattening. This can be done by individual feeding and careful control of the amount of meal given, but a more practical method is to replace some of the grain by a relatively indigestible constituent such as alfalfa chaff or chaffed peanut hay, which can be supplied to

appetite. Two trials were made to demonstrate this. In the first, under controlled experimental conditions, 5, 10 and 15 per cent. of the ration of meatmeal and grain was progressively replaced by alfalfa chaff from 100 to 200 lb. liveweight. The replacement reduced the rate of growth by 12 per cent. and thickness of back fat was less. In the second trial, under field conditions, the same replacement reduced rate of growth by 10 per cent. and thickness of back fat by 15 per cent. The economics of this procedure are discussed. Even in areas where carcass grade is not of first importance the use of cheap roughage may be financially advantageous.—T. D. Bell.

1327

WENIGER, J. and FUNK, K. Ausschlachtungsversuche und Schlachtmethode an Schweinen unter Berücksichtigung ihrer Futterverwertung [Slaughter experiments and slaughter methods with pigs, with reference to feed utilisation.] *Arch. Tierernährung*, 1952, **3**, 145-159. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

For the most part this is a critical examination of the literature dealing with slaughter experiments as a means of assessing feed utilisation and the effects of breed and type of pigs on the results. From a study of the results of analyses of 685 samples of pork it is shown that there is a close correlation, $r = +0.995$, between dry matter and fat percentages:

$$\text{Fat per cent.} = \frac{\text{Dry matter per cent.} - 22.5}{0.76} \pm 1.5,$$

and from 142 analyses of carcasses, excluding stomach, intestinal, gall bladder and bladder contents, that there is a close correlation,

$$r = +0.85 \pm 0.073,$$

between percentage total fat content and the percentage fat in the ham:

$$\text{Total fat \%} = \frac{\text{Percentage fat in ham} + 5.88}{1.14} \pm 5.2.$$

Figures are given for the amounts of dry matter, protein, fat and ash expressed in g. in 9 pigs of 3 breeds of approximate liveweight 30 kg. and in 11 pigs of 4 breeds, approximate liveweight 40 kg. These figures are considered necessary as reference data for pig fattening trials, since such trials usually start with pigs of liveweight 30 to 40 kg.

W. Godden.

1328

STRUCK, M. Fütterungsfehler (Eiweissmangel) führt zur Braunfärbung des Fettes und Auftreten des Fäkalgeruches bei Schlachtschweinen. [An error in feeding (protein deficiency) causes brown pigmentation of fat and the appearance of faecal smell in pork car-

cases.] *Berl. Münch. tierärztl. Wochenschr.*, 1953, **66**, 277-278. [Zentralschlachthof, Hamburg.] English summary.

In a single year 48 pork carcasses, weighing nearly 7 metric tons, were condemned at the Hamburg slaughterhouse alone on account of discoloured fat and faecal odour of the flesh when cooking tests were made. Eight pigs from one herd had been fed on milo grain only, 11 from another on swill and fishmeal. It is suggested that such rations supply incomplete or poorly absorbed proteins and that liver damage insufficient to cause jaundice or visible cirrhosis is to blame for the defects of colour and odour. Heavy loss to the farmer can be avoided by better feeding.—W. M. Deans.

1329

BETTS, A. O. and BEVERIDGE, W. I. B. Virus pneumonia of pigs. The effect of the disease upon growth and efficiency of food utilisation. *Vet. Rec.*, 1953, **65**, 515-521. [Dept. Animal Pathol., Cambridge.]

The weight gains and feed conversion ratios to bacon weight were recorded in comparable groups, control and infected with virus pneumonia, of Essex and Essex \times Large White pigs in 2 experiments, one in summer and the other in winter. Infection was established by the intratracheal injection of a standard amount of a suspension of pneumonic lung. The ration consisted of barley-meal 40, miller's offals 30, maize-meal 20 and fish-meal 10.

In the summer experiment the mean daily weight increment to 200 lb. liveweight was 1.29 lb. for the control and 1.11 lb. for the infected pigs, the corresponding feed conversion ratios being 3.39 and 4.25:1. In the winter experiments, in which the housing conditions were unsatisfactory, the corresponding daily weight increments were 1.19 (control) and 0.92 lb. (infected) with conversion ratios of 3.85 and 4.90:1, respectively. These differences were in the main due to the uneven performances of the infected pigs, and in the summer experiment particularly, culling would have left animals with satisfactory performances.

During the experiments there was little or no evidence of illness, and the only signs other than sub-optimum growth were coughing and periods of inappetence, with accompanying rectal temperatures usually exceeding 104.5° F. The adverse effects were most noticeable between 19 and 24 weeks of age.

On the basis that at least 50 per cent. of the pigs in Great Britain have lesions of virus pneumonia at slaughter, the overall economic loss from the disease is computed to be 12.5 per cent. of the annual pig production of over £15 million.

BRADFORD, G. E., CHAPMAN, A. B. and GRUMMER, R. H. **Performance of hogs of different breeds and from straightbred and crossbred dams on Wisconsin farms.** *J. Animal Sci.*, 1953, **12**, 582-590. [Dept. Genetics, Wisconsin Agric. Exp. Stat., Madison.]

The data on 2827 litters of pigs farrowed and reared by gilts between 1947 and 1952 were studied. The breeds were Spotted Poland China, Duroc, Chester White and Poland China and crosses between these.

Between breeds the only significant differences were in the Poland China, which produced smaller litters, and the Spotted Poland China, which had a lower mortality rate. Crossbred gilts had litters with lower mortality than purebred, and hence a greater litter weight at 5 months, but there was no difference in individual weights. This was the only advantage shown by crossbred gilts.

CONGIU, S. Indagini sulla resa al macello, sulla distribuzione ponderale e sulle correlazioni fra le diverse parti del corpo del dromedario somalo. [Particulars on the dressed carcass, fat distribution and correlations between the weights of the different organs of the Somali dromedary.] *Zootec. Vet.*, 1953, **8**, 188-191. [Ist. Sierovaccinogena, Merca.]

The camel is still of great economic importance as a beast of burden and as the main source of meat supply in the northern arid regions of Somalia. Only mature animals are slaughtered, usually about 10 to 12 years old. Poorly nourished animals are refused. The fat, particularly of the hump, is greatly prized. Data were obtained from the slaughter of 50 males and 100 females at the Merca abattoir. Average liveweight was 554 kg. for males and 574 kg. for females, with dressing percentages of 56.7 and 54.14, respectively. There was great variation in the weight of the humps, from 3.5 to 93 kg., average 20.2 kg. in females and from 3.0 to 45 kg., average 15.25 kg., in males. The liver, 12 kg., weighed more than the other organs combined. It is suggested that slaughter at 4 to 5 years of age would yield

meat of better quality, more suited to European taste. [Tables of results and of the correlations between liveweight and weights of different organs are referred to, but not presented. They are obtainable from the author.]—T. D. Bell.

SHILOV, I. A. K voprosy o pitanii rechnogo bobra (Castor Fiber L.) [The problem of the nutrition of the river beaver (*Castor fiber*, L.).] *Zool. Zh.*, 1952, **31**, 924-931. [Kaf. Zool. Pozvon., Mosk. Gosud. Univ.]

The basic food of the river beaver depends to a large extent on geography. The preferred foods in the regions studied are willow and poplar; the preference is determined by their high dietary value. The fact that the beavers in the northern territories feed on birch and other substitute foods is due to absence of willow and poplar. The change-over to feeding on grass plants is from 2 to 3 months later in the north than in the south; the reverse change back to a diet of bark is from 1 to 2 months earlier in the north than in the south. Thus the beavers in the north are compelled to subsist on plants of low food value during the greater part of the year. (From Author's summary.)—W. Hughes.

1338

SHILOVA-KRASOVA, S. A. O pitanii ezhei (*Erinaceus Europaeus* L.) v yuzhnykh leasakh. [The nutrition of the hedgehog (*Erinaceus europaeus*, L.) in the southern forests.] *Zool.*

Zh., 1952, **31**, 944-947. [Kaf. Zool. Pozvon., Mosk. Gosud. Univ.]

Experiments on 2 groups of hedgehogs found in 2 different localities, 222 in one and 40 in the other, showed that the basic food of hedgehogs during the summer and autumn months was insects. Mice and lizards formed a very small percentage of the total food. The most popular insect was the May beetle (*Melolontha hippocastani*), which formed 76 per cent. of the insects eaten. During May the hedgehog lives practically exclusively on this beetle, and can eat up to 100 of them in 24 hr. Hedgehogs will also eat the beetle larvae, digging them up in order to do so. A list is given of all the insects in the diet and the proportions in which they occur.—W. Hughes.

MCDONALD, M. W. and McClymont, G. L. Condensed whale solubles. An efficient replacement for meatmeal in chicken rations. *Agric. Gaz. N.S.W.*, 1953, **64**, 303-304; 324-325. [Poultry Exp. Stat., Seven Hills.]

Whale solubles were tested as a substitute for meatmeal in chick rations with high or low contents of the vitamin B complex.

Rations low in B vitamins gave very poor growth, especially if all the meatmeal was replaced by whale solubles, but if the supply of B vitamins

was adequate whale solubles could replace some or all of the meatmeal without affecting growth adversely. If the meatmeal content was below 10 per cent., additional Ca was required, and if it was below 6 per cent. P was required also.

P. C. Jowsey.

1343

PATRICK, H. Supplements for a "meat-scrap" type chick ration. *Poultry Sci.*, 1953, **32**, 570-572. [Poultry Dept., Univ. Tennessee, Knoxville.]

Groups of 10 day-old New Hampshire chicks from hens given a meat scraps ration were themselves given a basal ration containing 18 per cent. meat scraps. In experiment 1, the following supplements were given, replacing an equal weight of maize: 10 per cent. soya bean oilmeal, 20 p.p.m. nicotinic acid, 0.2 per cent. choline, 5 per cent. brewer's yeast, 3 p.p.m. folic acid, 1 mg. vitamin B₁₂ per 100 lb. feed.

Average liveweights of the chicks at 5 weeks of age were 178 (control), 279, 201, 180, 223, 186 and 193 g., respectively. In experiment 2, the groups were: control, 10 per cent. soya bean oilmeal, 0.3 per cent. methionine, 0.3 per cent. lysine, 5 per cent. casein, 20 p.p.m. nicotinic acid plus 3 p.p.m. folic acid, 0.3 per cent. methionine plus 0.2 per cent. choline. Average liveweights at 5 weeks were 283, 473, 300, 398, 460, 315 and 320 g., respectively. In experiment 3, the groups were: control, 0.3 per cent. lysine, 10 p.p.m. bacitracin, 10 p.p.m. bacitracin plus 0.3 per cent. lysine, 2 p.p.m. procaine penicillin, 2 p.p.m. procaine

penicillin plus 0.3 per cent. lysine, 10 p.p.m. terramycin, 10 p.p.m. terramycin plus 0.3 per cent. lysine, 20 p.p.m. aureomycin, 20 p.p.m. aureomycin plus 0.3 per cent. lysine, 10 per cent. soya bean oilmeal, 5 per cent. casein. Average liveweights at 5 weeks were 198, 302, 266, 326, 268, 332, 312, 340, 264, 328, 328 and 318 g., respectively. This experiment was repeated in duplicate, but omitting the last 2 groups; corresponding average liveweights at 5 weeks were 196 and 309, 267 and 358, 268 and 304, 273 and 386, 286 and 362, 293 and 386, 293 and 308, 324 and 392, 299 and 334, 324 and 372 g.—M. J. Head.

1344

RENNER, R., CLANDININ, D. R. and ROBBLEE, A. R. **Action of moisture on damage done during over-heating of soybean oil meal.** *Poultry Sci.*, 1953, **32**, 582-585. [Poultry Div., Univ. Alberta, Edmonton.]

The soya bean oilmeals used in this trial were produced experimentally by autoclaving for 4 min. at 15 lb. pressure; for 30 min. at 15 lb.; or for 4 hr. at 15 lb. with 0, 25, 50 or 100 per cent. of water added. Practical starter rations containing the meals were given to groups of day-old Single Comb Leghorn chicks for 3 weeks and the group average liveweights were 204, 209, 135, 166, 161 and 163 g., respectively. When the meals were given with a semi-synthetic ration, the group average liveweights were 178, 175, 72, 102, 126 and 139 g., respectively.—M. J. Head.

SLINGER, S. J., PEPPER, W. F. and HILL, D. C. **Value of methionine supplementation of chick and poult diet containing a high percentage of wheat.** *Poultry Sci.*, 1953, **32**, 573-575. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

The birds were grouped by weight. In the first experiment 20 day-old Columbia Red chicks were housed in battery brooders and given a ration containing about 61 per cent. ground wheat to 52 days of age, then 54 per cent. wheat to 70 days, the methionine contents being 0.34 and 0.29 per cent., respectively. Supplements of 0.5, 0.75 and 1.0 lb. DL-methionine per ton of feed were given, but no improvement in chick weight was observed. The experiment was repeated with a ration containing 53 per cent. ground wheat for 100 day-old Columbia Red chicks housed on an open floor with wood shavings as litter, and with a ration containing 21 per cent. ground wheat for 33 male and 37 female day-old Broad Breasted Bronze turkey poults housed on an open floor, but there was no improvement in liveweight increase.

EBBELL, H. **Der Einfluss einer Beigabe von Methionin und eines Terramycin-Produktes auf das Kükenwachstum. [Effect of supplements of methionine and a terramycin product on the growth of chicks.]** *Arch. Geflügelk.*, 1953, **17**, 145-154. [Ovomaltine Farm, Oberwangen, Berne.] English summary.

Four groups of day-old chicks, 287 in all, were given an approved all-mash ration; one group acted as a control and the others had the ration supplemented with 0.15 per cent. DL-methionine or with 0.1 per cent. of a vitamin B₁₂-terramycin concentrate given for 6 weeks to one group and 8 weeks to another. The birds were separated by sex after 6 weeks and the experiment terminated after 10 weeks.

The addition of methionine gave a growth response, as compared with the controls, of 2 per cent. with the cockerels and 6.5 per cent. with the pullets. The terramycin supplement for 6 weeks gave responses of 5 and 12 per cent., respectively, and no further benefit resulted from continuing the supplement for 8 weeks. In general the terramycin supplement gave more uniform birds, a better quality in the finished broiler and fewer rejects at 6 weeks.—W. Godden.

ANDERSON, G. W., SLINGER, S. J. and PEPPER, W. F. **Bacterial cultures in the nutrition of poultry. 1. Effect of dietary bacterial cultures on the growth and cecal flora of chicks.**

ANDERSON, G. W., SLINGER, S. J., PEPPER, W. F. and HAUSER, M. M. **2. Effect of dietary coliform cultures on the growth and cecal flora of poults.** *J. Nutrition*, 1953, **50**, 35-46; 47-57. [Dept. Bacteriol., Ontario Agric. Coll., Guelph.]

1. Sixteen groups of 20 male chicks were given a basal diet supplemented with one of 5 bacterial cultures isolated from the caeca of chicks, with or without 10 p.p.m. procaine penicillin. Pooled caecal contents from 5 birds were well mixed and 1 g. was used for plating; pH estimations were made on the remainder of the sample. The cultures used were of typical *Bacterium coli*, 2 strains of atypical *Bact. coli*, micrococci and anaerobes. The basal diet supplemented with penicillin alone caused increases in weight which were not significant. One of the atypical *Bact. coli* cultures caused a significant weight increase without penicillin, and all 3 coliform cultures with penicillin gave greater weights than without, or than penicillin alone. Two of these increases were significant and indicated a synergistic reaction between the corresponding culture and the antibiotic. The micrococci without penicillin depressed the weight of the chicks, but this inhibitory effect was completely removed by administration of penicillin with the culture. No weight increase was observed with or without penicillin when the anaerobes were given, but feed efficiency was greater.

In a second experiment 10 groups of 20 chicks of both sexes were given the basal diet as in experiment 1 either alone or supplemented with a mixed culture of the coliform bacteria used separately in experiment 1, or the filtrate or the washed cells from the centrifuged mixed culture. Part of each group received penicillin as well. A significant increase in weight was recorded only in the group receiving filtrate plus penicillin. In both experiments penicillin tended to reduce the pH and the numbers of bacteria which could be isolated from the caeca of the chicks. When, however, the antibiotic was given with the cultures, the pH reduction was not so marked. Changes in the numbers of aerobes, anaerobes, coliform bacteria, lactobacilli and enterococci resulted from giving the cultures with or without penicillin. In a few cases the changes were significant but in no case was there a clear shift to the type of culture used. It is suggested that the association of greatest weights and feed:gain ratios with the lowest enterococci counts may be of importance.

2. A mixed culture of coliform bacteria isolated

from the caeca of chicks receiving penicillin caused a non-significant increase in weight of poults when given in conjunction with a practical ration and penicillin. Washed viable cells from this culture gave similar results. Neither the filtrate nor the killed cells from this culture caused any change in weight. A typical *Bact. coli* culture produced a significant increase in weight. When given along with penicillin this culture slightly enhanced the activity of the penicillin. An atypical *Bact. coli* culture increased the weight of female poults, but this increase approached significance only at the 5 per cent. level. No change was found when this culture was given with penicillin. As before, the pH of caecal contents was reduced by penicillin. The weight increases caused by the addition of penicillin and coliform cultures to the diet could not be related to the changes in numbers of the types of bacteria isolated from the caeca of the poults.—M. J. Masson.

ROMOSER, G. L., SHORB, M. S. and COMBS, G. F. **Effect of orally administered penicillin-resistant microorganisms on growth of chicks.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 17-21. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Groups of fifteen 20-day-old chicks of both sexes were used to compare the growth effects of a practical ration with supplements as follows: a mash fermented with *Aerobacter aerogenes*, isolated from the caeca of chicks, at levels of 0.4 and 2.0 per cent. of the practical ration; 10 p.p.m. penicillin; or dried *A. aerogenes* or both. Increased weight gains resulted from addition of the mash to the basal diet at both levels; with 2.0 per cent. increases were comparable with those on the diet with penicillin alone. Dried *A. aerogenes* added to the diet gave weights greater than those obtained from the diet and penicillin alone and the biggest weight increases of all were reported for the group receiving both dried *A. aerogenes* and penicillin. The experiment lasted 4 weeks.

A second experiment showed that when dried cultures of *Bacterium coli* or *A. aerogenes* were added to the basal diet without lactose or penicillin, growth was slightly improved. The addition to the diet of 3 per cent. lactose and 10 p.p.m. penicillin alone caused a marked increase in growth, and the addition of either *Bact. coli* or *A. aerogenes* as well caused an even greater increase. When both cultures were given with lactose and penicillin the greatest increase of all was found.

BLETNER, J. K., CLARK, T. B., WEAKLEY, C. E. (Jr.) and VANLANDINGHAM, A. H. **The effect of sulfaquinoxaline in different ration formulations on growth and feed efficiency of**

coccidia-free chicks. *Poultry Sci.*, 1953, **32**, 733-739. [W. Virginia Agric. Exp. Stat., Morgantown.]

After 3 weeks on starter mash, 16 groups of 10 coccidia-free chicks were given experimental rations for 28 days. Four rations were used in a 4 × 4 Latin square layout: rations 1 and 4 were similar to commercial broiler rations in use before the introduction of high energy rations, ration 2 contained more crude protein and less fibre and ration 3 was a typical early high-energy ration. Sulphaquinoxaline was given at the rate of 0.00625 and 0.0125 per cent. with each ration, but was found to have no effect on growth. At the therapeutic level of 0.05 per cent., signs of toxicity were observed.

Some unexplained differences in growth occurred in birds in different parts of the battery, and emphasis is laid on the importance of sufficient replication. Fasting the chicks for 12 hr. before weighing had no effect on this variability.

GERARD, W. E., READ, D. C. and PENSACK, J. M. **A comparative evaluation of several antibiotics on chick and swine growth.** *J. Agric. Food Chem.*, 1953, **1**, 784-788. [Res. and Development Dept., Commercial Solvents Corp., Terre Haute, Ind.]

In a series of 7 trials chicks housed on wire screen floors were fed from day-old to 4 weeks of age on a ration of soya bean meal 24, oats 10, wheat middlings 5, fishmeal 3, alfalfa meal 2.5, minerals 4, *DL*-methionine 0.05, choline chloride 0.02, riboflavin supplement, vitamin B₁₂ supplement, vitamin A and D supplement, nicotinic acid, Ca pantothenate and yellow maize meal to 100. Other chicks received the same ration supplemented with 2 g. per ton of the 1-N-methyl-1:2-diphenyl-2-dihydroxyethylamine salt of penicillin G (I), each treatment being given to duplicate lots each of 20 chicks. The mean increase in weight with (I) in each trial ranged from 23 g. to 65 g. In each trial one other antibiotic was tested at a series of levels from 1 to 50 g. per ton of ration. Growth stimulation was obtained with bacitracin, aureomycin, terramycin, erythromycin and "antibiotic B" [no detail given], though the stimulation was less, or only obtained at higher levels, than with (I). No growth stimulation was obtained with 1-4-thiazolidone-2-caproic acid (Antibiotic A).

In a bacon pig feeding trial a group of 13 weanling pigs of average weight 45 lb. were housed with access to a half-acre plot of clover pasture, with shelled maize always available, and also a pelleted supplement of soya bean meal 80, minerals 14, fishmeal 3, condensed fish solubles 1, choline chloride 0.2, riboflavin, B₁₂ and vitamin A and D

supplements, nicotinic acid and Ca pantothenate. This group took 113 days to reach a mean bodyweight of 200 lb. and used 3.33 lb. feed per lb. liveweight gain. A parallel group having the pellets supplemented with 5 g. (I) and 25 g. bacitracin per ton reached 200 lb. bodyweight in 104 days, using 3.15 lb. feed per lb. liveweight gain. Other groups receiving aureomycin or erythromycin also showed faster growth than the control group, but with smaller gains in feed conversion efficiency than the group supplemented with "penicillin-bacitracin". The maize and the supplement were eaten in the proportion of about 7 to 1.—K. J. Carpenter.

FRÖLICH, A. **Försök med antibiotika till kycklingar.** [I. Som fodertillskott till allsidiga foderstater. **[Experiments with antibiotics for chicks. 1. As supplements to complete rations.]** *Kgl. Lantbruksakad. Tidskr.*, 1953, **92**, 151-163. [Stat. Hushjursförsök, Uppsala.] English summary.

The literature and theories on the mode of action of antibiotics are briefly reviewed and the results of all experiments at the State Experiment Station at Uppsala are summarised and discussed.

By-products of stated residual antibiotic value were more effective as growth stimulants than were "pure APF" products. In the experiments medicinal standard procaine penicillin and aureomycin were used, but the bacitracin and terramycin were relatively impure concentrates guaranteed to have 11 g. antibiotic per kg. For each of these antibiotics the percentage increase in weight gain to 4 weeks of age and the percentage of saving of feed per unit weight gain are shown for different amounts of antibiotic per ton of feed. These ranged from zero to about 25 per cent.; there was no evidence of injury. On the average of different concentrations, the effect of penicillin was greatest during the first week and decreased with age. It differed from one experimental room to another, and over 9 months showed a remarkable rise in the amount required to give a response.

MÜLLER, W. Zulage von Antibiotica-Präparaten zu einer handelsüblichen Mastmischung für Hähnchen. Bericht über einen auf Veranlassung der Vereinigung Schweiz. Futtermittelfabrikanten (VSF) im Parc avicole Coppet (Besitzer: H. Séguin) durchgeführten Versuch. [Addition of antibiotic preparations to a commercial fattening meal for cockerels. Report on an experiment made in the Parc avicole Coppet (proprietor H. Séguin) at the request of the Swiss Feedingstuffs Manufacturers Association (VSF).] *Arch. Geflügelk.*, 1953, 17, 201-208. English summary.

The antibiotics used were terramycin, penicillin, aureomycin, terramycin plus penicillin and aureomycin plus penicillin. Four groups of 20 cockerels, 7 weeks old, were used for each supplement to a standard ration and 4 groups served as a control. The feeding lasted for 26 days. All the antibiotics improved growth rate and feed efficiency; terramycin gave the best results. When mixtures of antibiotics were used there was no evidence of any additional effect. Allowing for the cost of the antibiotics the improved efficiency reduced the feed costs per kg. gain by 6 to 15 per cent. compared with that of the control groups.—W. Godden.

1357

SAXENA, H. C., STARR, M. E., BLAYLOCK, L. G., CARVER, J. S. and MCGINNIS, J. Effect of dietary penicillin on the efficiency of protein utilization by chicks. *Arch. Biochem. Biophys.*, 1953, 44, 346-350. [Dept. Poultry Sci., State Coll. Washington, Pullman.]

Eighteen groups of 10 day-old New Hampshire × White Olympian chicks, obtained from a flock receiving fishmeal in the ration, were given feeds containing 15, 18 and 21 per cent. protein with or without 3 p.p.m. diamine penicillin, 1100 units per mg. All feeds were adequate in all known vitamins. The N retention of each group of chicks was studied for two 7-day periods, beginning on the 14th day of experiment.

At 4 weeks of age, the groups given penicillin were significantly heavier than their controls on each protein level. All groups on the lowest protein level were lighter than the others, but the increase due to penicillin feeding was similar at all protein levels. Feed efficiency was better at the 18 and 21 per cent. protein levels regardless of

supplementation, but penicillin improved efficiency at all protein levels. Small but not statistically significant increases in N retention were found in the birds receiving the penicillin supplement at the lowest protein level.—M. J. Head.

SAXENA, H. C., BLAYLOCK, L. G., STADELMAN, W. J., CARVER, J. S. and MCGINNIS, J. Effect of penicillin on growth, feed efficiency and fattening of turkeys. *Poultry Sci.*, 1953, 32, 721-726. [Dept. Poultry Sci., State Coll. Washington, Pullman.]

Sixteen groups of 30 day-old Broad Breasted Bronze turkeys, both sexes, were given a maize, soya bean and herring meal starter ration to 8 weeks of age, 8 groups receiving 3 p.p.m. diamine penicillin in addition. At 8 weeks of age, 25 birds from each group were transferred to houses on range and given a mixed developer meal; half of those birds which had received antibiotic to 8 weeks of age continued to receive it while the remainder did not, and half of the birds which had not received the diamine penicillin began to get it.

The effect of the antibiotic supplement was greatest when it was given for the entire experimental period of 24 weeks, by which time the males had gained 809 g. and the females 488 g. more than the control birds. To 8 weeks of age antibiotic supplementation increased the growth of both sexes by 178 g. over the controls. Supplementation from 8 to 24 weeks of age also gave an increase in growth over the controls. Feed efficiency was considerably improved by the antibiotic, and carcass quality, judged by subcutaneous fat deposition, was improved. An analysis of the economics of giving the supplement showed that it could profitably be given throughout the life of a fattening turkey.—M. J. Head.

1359

SWICKARD, M. T., HARKIN, A. M. and MARSDEN, S. J. Palatability of turkeys fed experimental diets containing aureomycin and fish products. *Poultry Sci.*, 1953, 32, 726-729. [Bur. Human Nutrit., U.S. Dept. Agric., Washington 25, D.C.]

Turkeys reared on a commercial mash, which included 5 per cent. of menhaden fishmeal, were killed at 14, 16 and 26 weeks of age, and after storage at 0° F. they were roasted and the meats were tasted by an expert panel. Parallel birds that had received 10 mg. aureomycin hydrochloride per kg. mash were tasted at the same time.

Some off-flavour was noticed in most of the younger birds, but in only a few of those killed at 26 weeks. Inclusion of the antibiotic in the ration did not affect eating quality at any age.

YOUNG, R. J., GILLIS, M. B. and NORRIS, L. C. **An unidentified factor in peanut meal required by the chick.** *J. Nutrition*, 1953, **50**, 291-297. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Chicks were fed from day-old to 4 weeks of age on a ration of casein 25, hydrogenated vegetable fat 2.5, cellophane 3, minerals 4.2, choline 0.15, purified vitamins and maize starch to 100. Growth on this ration was poor, but was increased by the addition of arginine, the maximum effect being reached when the ration contained 1.7 per cent. arginine in all. Even at this level growth was subnormal, with a mean chick weight of 275 g. at 4 weeks of age. Performance was not improved by using less highly purified samples of casein.

Similar rations containing 15 per cent. groundnut meal, extracted for 48 hr. with ethanol and for 24 hr. further with methanol, which was added at the expense of casein and starch so as to keep the total protein constant, supported faster growth, with chicks reaching a mean weight of 325 g. In the presence of additional arginine the same performance was obtained with only 5 per cent. groundnut meal. Analysis suggested that no other amino-acid deficiency could be corrected by the addition of groundnut meal and it was concluded that this material supplied an unknown growth substance essential for the chick.—R. J. Carpenter.

1361

CARVER, D. S. and JOHNSON, E. L. **Unidentified growth factors for the chick in vegetable oils and fatty acid concentrates.** *Poultry Sci.*, 1953, **32**, 701-705. [Dept. Poultry Husb., Iowa State Coll., Ames.]

Groups of day-old chicks [number and breed not specified] were given adequate nutrients with a synthetic ration based either on casein and glucose, containing 0.05 per cent. fat, or on soya bean protein and glucose, containing 0.04 per cent. fat, and some groups were given 4 per cent. maize oil in addition. Liveweight at 4 weeks of age was increased and mortality was low in groups given the oil supplements. In a second experiment, supplements of 4 per cent. refined maize oil, 4 per cent. crude maize oil or 4 per cent. soya bean oil were added to the ration of soya bean protein and glucose; the average liveweights at 4 weeks of age were 136 g. for the basal ration and 205 g., 201 g. and 184 g., respectively, with the supplements, the respective feed efficiencies being in units of feed per unit gain 2.85, 2.23, 2.25 and 2.21. In a further series of experiments, supplements of crude maize oil, wheat germ oil, oleic acid and linoleic acid, either alone or combined, were added to the same basal ration and all increased growth rate to 4 weeks of age; supplements of stearic acid did not increase growth rate. These

unsaturated oils are thought to contain growth-promoting substances for the chick, oleic acid and wheat germ oil being especially potent.

M. J. Head.

1362

MILLER, O. N. **An unrecognized nutritional factor (cornstarch) required by the duck.** *J. Nutrition*, 1953, **50**, 13-22. [Dept. Biochem., Univ. Texas Med. Branch, Galveston.]

Thirty-one newly hatched ducklings were housed in cages with raised screen floors and fed on a ration of casein 18, gelatine 10, maize oil 10, cellulose 4, minerals 5, vitamins A, B₁, B₆, D, E, and K, biotin, Ca pantothenate, folic acid, nicotinic acid and riboflavin, and maize starch to 100. At 32 days of age the birds had a mean weight of 990 g., and were of good general appearance. Birds fed on the same ration with sucrose replacing maize starch weighed 780 g. and appeared less healthy.

Both groups were killed, and at post-mortem examination 21 per cent. of the maize starch group showed lesions of pancreatic fibrosis, and 87 per cent. of the sucrose group.

In further trials neither vitamin B₁₂ with inositol nor methionine was of value in preventing the onset of the condition in the birds receiving sucrose. The addition of 10 per cent. of maize starch was sufficient to prevent its appearance, and sugar refiner's "mud" was partly effective at low levels.

It is considered possible that the active material in commercial maize starch may be identical with Schwarz's "factor 3" (Abst. 1037, Vol. 22), which has been reported to be present in some strains of yeast and to prevent liver necrosis in young rats.

EGG PRODUCTION

1365

TITUS, H. W. **Variation of egg production and hatchability.** *Poultry Sci.*, 1953, **32**, 593-601. [Lime Crest Res. Lab., Limestone Products Corp. America, Newton, N.J.]

N.A. and R., January 1954

The results of a uniformity trial on egg production and hatchability are presented. The birds were kept in 24 pens of 25 birds and the means for both variables are given, along with estimates of variability. [The individual bird is used as the unit of variability, although the birds were fed, housed, and mated in groups of 25]. From these results, estimates are made of the differences which would be detected at given significance levels, for differing average numbers of eggs and for differing average hatchability. Finally, it is shown how to estimate, if the variability is assumed to be known, how many birds would be required to detect a difference of a given size, and an example is given.—A. W. Boyne.

1366

ROSENBERG, M. M. **A study of B-grade and refinery B-molasses in layer rations.** *Poultry Sci.*, 1953, **32**, 605-612. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

B-grade molasses is the portion of the massecuite forcibly removed from the centrifugal sugars during the second centrifuging; low-grade sugar and blackstrap molasses are obtained from it in the third strike. It is a viscous liquid and has an approximate composition of sucrose 48, water 20 and impurities 32 per cent., the latter consisting of about equal parts of reducing sugars, organic non-sugars and ash. One part of the molasses compounds was mixed with 5 parts of ground dried bagasse pith. Refinery B-molasses was also tested, since it is produced by sugar refiners in the temperate zones.

In trials with 7 groups of 10 New Hampshire pullets, rations were given containing 29.6, 38.8 and 47.9 per cent. B-grade molasses (groups 1 to 3) or refinery B-molasses (groups 4 to 6) over a 20-week period. The egg production of the groups was 65, 63, 64, 66, 59 and 43 per cent., compared with 71 per cent. for the controls. Groups 3 to 6 inclusive laid significantly smaller eggs than the controls; feed efficiency fell as the concentration of sugar by-product in the ration increased. The bodyweight of the experimental groups did not increase as much as that of the controls and the hatchability of the eggs was lower on rations containing sugar by-products.

In the second trial, 16 groups of 9 New Hampshire pullets were given rations without or with 29.6, 38.8 or 47.9 per cent. B-grade molasses along with 5.9, 7.7 or 9.6 per cent. bagasse pith for 16 weeks. Egg production on the 2 higher levels of sugar by-product feeding was lower than in controls but no statistically significant effect on egg size was observed. Liveweight gain and feed efficiency were significantly depressed as the proportion of sugar by-product in the ration was increased.—M. J. Head.

Vol. 24, No. 1

1367

FLETCHER, J. L., BARRENTINE, B. F., DREESSEN, L. J., HILL, J. E. and SHAWVER, C. B. **The use of ferrous sulfate to inactivate gossypol in diets of laying hens.** *Poultry Sci.*, 1953, **32**, 740-742. [Dept. Animal Husb., Mississippi Agric. Exp. Stat., College Station.]

The 3 groups of 11 New Hampshire hens used in this trial received the following rations: normal control, control with 10 per cent. cottonseed meal replacing 10 per cent. protein concentrates, and the same plus 0.5 per cent. ferrous sulphate. The cottonseed meal consisted of equal parts of hydraulic- and solvent-extracted meal and contained 0.3 per cent. free gossypol. All the eggs from each group were stored for 60 or 150 days at 34° F.; 5 out of 90 eggs from the first group had slightly dark yolks, and 6 out of 117 from the third group.—M. J. Head.

1368

SIZEMORE, J. R., LILLIE, R. J., DENTON, C. A. and BIRD, H. R. **Influence of aureomycin in the chick diet upon subsequent reproductive performance of laying hens.** *Poultry Sci.*, 1953, **32**, 618-624. [Bur. Animal Indust., Agric. Res. Admin., Beltsville, Md.]

All the Rhode Island Red chicks used in this trial were given a similar mash and were kept on sawdust litter to 8 weeks of age. From this age to 22 weeks, groups 1 and 2 received the Connecticut broiler ration (CBR), groups 4 and 5 CBR plus antibiotic, groups 7 and 8 a mixed maize and soya bean ration (CS) and groups 10 and 11 CS plus antibiotic; all groups had mixed wheat and maize free choice in addition. The antibiotic was supplied as 0.5 per cent. of a supplement containing 1.8 mg. vitamin B₁₂ and 1.8 g. aureomycin hydrochloride per lb. At 22 weeks of age, representatives of each group were placed in each of 6 wire-floored houses and 8 sawdust litter houses, making groups of 40 and 36 for the respective types of house. The groups on sawdust litter were given a standard laying mash containing ample vitamin B₁₂ and the groups on wire floors a maize and soya bean ration deficient in vitamin B₁₂, with or without antibiotic.

For the rearing period on range up to 22 weeks of age, the birds given antibiotic grew faster than the controls, but the supplement had no effect on age at sexual maturity or on mortality. During the laying period, no effect of chick diet or laying diet was found on egg production, mortality, egg weight or shell thickness. The hatchability of fertile eggs was greater from hens which had received antibiotic in the rearing period, even when aureomycin was included in the laying ration; this effect was not observed when the laying ration contained adequate vitamin B₁₂.

The eggs from different groups showed only small differences in their vitamin B₁₂ content.

1369

SLINGER, S. J., MORPHET, A. M., HUNT, E. C. and PEPPER, W. F. **Effect of penicillin on the reproductive performance of turkeys.** *Poultry Sci.*, 1953, **32**, 660-669. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

One young tom was placed in each of 12 groups of 9 Broad Breasted Bronze turkeys in their first laying year and 2 groups of 10 in their second laying year. All birds were in the same house. They were given an all-mash ration, starting 8 weeks before eggs were saved for hatching, and their houses were artificially lit to give a 14-hr. day. Even-numbered groups received a supplement of 2 g. crude procaine penicillin G per ton feed from 28 January to 16 June. The supplements were then given to the odd-numbered groups until the end of the experiment on 3 August. Eggs were hatched at regular intervals during the feeding trials.

The results showed that the penicillin supplement reduced hatchability, owing, apparently, to high incidence of early dead germs. The average group hatchability up to 16 June was 65.3 per cent. without and 50.4 per cent. with penicillin. After the reversal of the rations, the hatchability of eggs from birds receiving penicillin fell from 69 per cent. on 16 June to 22.3 per cent. on 4 August and that of the eggs from birds now receiving no supplement rose from 37.4 to 45.2 per cent. on 7 July and fell again to 24.6 per cent. on 4 August. This effect on hatchability was significant only at the 10 per cent. level in paired pens of birds, owing mainly to the high variation in the effect of supplements. The penicillin groups produced 314 eggs fewer between 1 April and 16 June than the unsupplemented groups. After the reversal of rations, the groups receiving penicillin laid 167 eggs more from 16 June to 4 August than those with no supplement. Egg production in both groups was declining at the time of change in ration. During the first period, the eggs from the penicillin groups weighed 2.27 g. less than those

from the unsupplemented groups ($P > 0.08$). The feed consumption of the penicillin groups was 5.4 per cent. below that of the unsupplemented groups.

ARSCOTT, G. H. and COMBS, G. F. **Further evidence for an unidentified hatchability factor in condensed fish solubles.** *Poultry Sci.*, 1953, **32**, 730-733. [Dept. Poultry Husb., Univ. Maryland, College Park.]

During a 13-week preliminary period, 200 New Hampshire pullets were given a maize-wheat-soya bean ration containing 0.5 g. iodinated casein per 100 lb. feed to deplete their reserves of vitamin B₁₂ rapidly. On the basis of the hatchability and fertility of eggs laid and the total egg production during the first 7 weeks of this period, the birds were equally divided into 5 groups. Groups 1 to 4 were housed on raised wire floors and group 5, the positive control, on litter. During the first 11 weeks of the 29-week experimental period groups 1 to 5 received, respectively, 0, 0.5, 0.75, 1.0 and 1.25 µg. vitamin B₁₂ per lb. feed and for the next 12 weeks 0, 0.4, 0.6, 0.8 and 1.0 µg.; for the remaining 6 weeks groups 2, 3 and 4 received 0.4, 0.6 and 2.0 µg. vitamin B₁₂ per lb. feed and groups 1 and 5 received 3 per cent. condensed fish solubles. At the end of period 2, i.e., after 23 weeks of experiment, the hatchability of eggs from groups 1 to 5 was 17, 33, 47, 44 and 70 per cent., respectively. At the end of period 3, the hatchability of eggs from groups 1 and 5 was 77 and 84 per cent., respectively, but that of the other 3 groups remained low.

A preliminary growth test on chicks hatched from eggs collected during period 3 indicated some degree of carry-over of the substance in the condensed fish solubles.—M. J. Head.

YAKSHIS, YA. YA. K voprosu ob izuchenii pitaniya khishchnykh ptits. [The problem of studying the nutrition of predatory birds.] *Zool. Zh.*, 1952, **31**, 948-950. [Kaf. Zool., Latvii Gosud. Univ.]

Using Folitarek's method (*J. Gen. Biol. USSR*, 1948, **9**, No. 1) for studying the diet of predatory

birds, in which a mask is placed on the young fledglings so as to collect scraps of the diet, observations were made of nests of eagles (*Aquila pomarina*) from which 16 objects of food were collected, and of buzzards (*Buteo buteo*), from which 504 objects were collected. From one nest, for example, 107 mammals, mainly voles and moles, 19 birds, 10 of which were larks, 6 reptiles and 15 amphibia were collected. Corresponding figures for another nest were 178, 29, 38, 105, the last being mainly frogs. It is considered that this method, in which none of the birds studied are killed, is superior to analysis of stomach contents.—W. Hughes.

BAUM, E. L. and WALKUP, H. G. **Some economic implications of input-output relationships in fryer production.** *J. Farm Econ.*, 1953, **35**, 223-235. [Dept. Agric. Econ., State Coll. Washington.]

The economic implications of the nutritional requirements of table poultry are examined. Two aspects of the problem are considered: possible variations in the daily ration from full feed conditions, and optimum weights of birds at sale.

A knowledge of the functional nature of feed requirements and of the relation between the market value of table poultry and the price of poultry feeds is necessary when deciding whether table birds should at all times have as much food as they will eat. It is suggested that when the table poultry: feed price ratio is 5:1 it pays to give the birds all the feed they will take during the early stages of growth but when they approach 9 to 12 weeks of age they should be given less than that amount.

Table poultry are produced in lots, and information on the relation between feed intake and live-weight increases is normally obtained from sample data. It is shown that corrections must be made in order to use these data for policy decisions on pens of birds.

The market value of table poultry per lb. changes little with increase in weight. It is therefore important to know the selling weights which tend to maximise the total weight of poultry obtained from a given intake of feed. Graphs are presented showing the relation between the increasing weights and profits of birds (1) when the price of feed increases while the market value of table poultry remains unchanged and (2) when the value of table poultry falls while the price of feed remains constant.

Consideration is also given to the economic implications of using high energy feeds to which antibiotics have been added and the concluding paragraphs deal with the possible effect of some of the fixed costs on management decisions.

WESTERMARCK, N. Svenska Österbottens jordbruk och befolkningsförhållanden i social-ekonomisk belysning. [Agriculture and population in Österbotten, Sweden, in the light of social economics.] *Acta agral. fenn.*, 1945, **61**, 1-244. [Helsinki.]

This district of east Sweden has close links of history and population with Finland. The report

describes in detail the geography, climate and population of the area; the standard of living, including diet, household expenditure and type and cost of education, general and technical; the general economic situation in terms of land values, banking and taxation. It goes on to an equally detailed description of the distribution and use of land, types of soil, size of holding; man power and wages; the use of horses and tractors and all the practices of crop and animal production. The financial side covers marketing, cooperative movements, and cash incomes from forestry, seal fishing and fur animals, against expenditure and running costs. The last section deals with women's work.—I. Leitch.

ASHE, A. J. **An economic analysis of large dairy farms, New York, 1949-50.** *Cornell Univ. Agric. Exp. Stat. Bull.* No. 887, January 1953, pp. 32. [Ithaca, N.Y.]

The data came from the records of 151 large dairy farms, average size 512 acres, of which 173 acres were in crops. The herds ranged from 41 to 246 cows, average 74.

Receipts from the sale of milk accounted for 67 per cent. of total receipts, as compared with less than 5 per cent. from the sale of crops. Feed, labour, equipment, and livestock accounted for 83 per cent. of the expenses. The average net cost of producing 100 lb. of 3.7 per cent. milk was \$4.10. Feed and labour accounted for 56 and 22 per cent., respectively, of the total cost. Labour efficiency increased as the number of cows per farm increased up to 100, but thereafter decreased.

The cost of producing 100 lb. milk was less in high-yielding herds than in low-yielding herds. Higher returns were obtained on farms where more than 50 per cent. of the milk was sold during the winter months. The conditions affecting costs and returns in producing milk are discussed in detail.

JONES, W. A. C. and IMPER, A. D. **Cattle costs—
summer 1952.** *North of Scotland Coll. Agric.
Econ. Rep.* No. 31, March 1953, pp. 11.

Records were collected for 53 groups of cattle, varying in size and composition, distributed throughout north and north-east Scotland; costs were calculated for the grazing period only. The cattle were mostly of the Aberdeen-Angus breed and its crosses, with a few pure Shorthorns and miscellaneous crosses. Taking into account the age and quality of the different grazings, the average net cost of grass was £5 4s. 1d. per acre, range £3 6s. 2d. to £6 7s. 4d. Animals graded off the grass were considered separately. They made an average gain of 2 cwt. and, at a total cost of £62 3s. 7d., left a net margin of £10 15s. 5d. per head for 16 weeks' grazing. This margin was much higher than in the previous year, owing chiefly to the rise in price per cwt. at slaughter. For cattle not finished on grass, 2-year-olds cost in all £51 19s. and one-year-olds £38 5s. 6d. per head by the end of the season. Because they were mostly on the cheaper grazings the cost of the 2-year-olds was 3s. 10d. and that of the one-year-olds 3s. 1d. weekly, for grass only, compared with 4s. 5d. for those graded off the grass.

The average grazing periods ranged from 16 weeks for those graded to 26 weeks for the younger animals.—W. Thomson.

1390

GODFREY, D. **Breeding cattle costs 1951/52.** *North of Scotland Coll. Agric. Econ. Rep.* No. 32, March 1953, pp. 16.

On 12 Caithness farms with an average herd of 16 cows the annual cost per cow was £30 2s. 3d. and per weaned calf £30 5s. On 12 upland farms and 7 lowland farms in the north of Scotland, of the same herd size, the respective costs were £32 2s. and £24 2s. 7d. per cow, and £31 7s. 10d. and £19 10s. 1d. per weaned calf; on 7 hill farms the herd average was 47 cows and the costs were £17 1s. per cow and £20 per weaned calf. Excluding subsidy, which was claimable in all except the lowland group, the margin of returns per weaned calf for the respective groups was —£3 6s. 8d., —£4 5s. 2d., +£6 15s. 7d. and +£3 14s. The range of costs and returns was wide, especially on the Caithness and upland farms. Costs on the lowland farms were lower,

chiefly because a larger proportion of cows suckled 2 calves. On the hill farms costs were least, chiefly because of lower feed costs, though calves were single-suckled and had the lowest valuation at weaning. The average number of calves reared in all groups was 84 per 100 cows. It is considered that the season was a good one and that this is one of the most important conditions influencing costs.—W. Thomson.

1391

PHILLIPS, R. and HUGHES, L. E. **Some aspects of losses in farm animals.** *Brit. Vet. J.*, 1953, 108, 458-472; 109, 33-38. [Dept. Animal Health, Univ. Coll. Wales, Aberystwyth.]

The information on which this paper is based was obtained from a number of sources, including reports issued by the chief veterinary officer of the Ministry of Agriculture, meat production records of the Ministry of Food and records of intakes into knackereries.

Particular reference is made to losses in the cattle population in the counties of Cardigan, Carmarthen and Pembroke. A study of the live-weights and gradings of all categories of cattle accepted on the hoof showed that three-quarters of the cows were in the lower grades (B and C), resulting in a substantial loss of potential beef. Cattle accepted as rejects and casualties represent a further loss.

Loss of condition during winter is considered an important source of loss, since part of the following summer grazing period is spent in making up the losses of the previous winter. The significance of the seasonal differences in intakes into 4 knackereries is discussed in detail.—J. N. Aitken.

1392

TERRILL, C. E. **The relation between sale price and merit in Columbia, Targhee and Rambouillet rams.** *J. Animal Sci.*, 1953, 12, 419-430. [U.S. Sheep Exp. Stat., U.S. Dept. Agric., Dubois, Idaho.]

The selling prices of 202 Columbia, 104 Targhee and 59 Rambouillet stud rams at public auctions from 1946 to 1951 were examined in relation to measures of merit. The highest correlation was between weight and price in yearlings. Correlations between price and grease fleece weight, clean fleece weight, type and condition were also significant. There was no constant relation between price and age. The results indicated that buyers attach real importance to production traits such as body and fleece weights and mutton conformation. It would be desirable to present more information on these lines at ram sales. This would facilitate improvement of flocks by selection.

T. D. Bell.

1393

BEYNON, V. H. **Bacon production from some home-grown foods.** *Agriculture, J. Minist. Agric. Engl.*, 1953, **60**, 206-210. [Dept. Econ., Univ. Bristol.]

The feed represents 80 per cent. of the cost of fattening a bacon pig. Estimated figures are

presented for fattening from 30 to 215 lb. live-weight on meal, or on a Lehmann system with potatoes or fodder beet. The use of roots does not impair carcass quality, and the saving per head was 17s. 4d. with potatoes and £2 11s. 4d. with fodder beet.—T. D. Bell.

BEDDOWS, A. R. **Observation on hoove, hoven, blown, or bloat taken from agricultural writings, 1716-1827.** *J. Agric. Soc. Univ. Coll. Wales, Aberystwyth*, 1952, **33**, 12-15. [Welsh Plant Breeding Stat., Aberystwyth.]

1395

WESTCOTT, R. W., MOORE, G. R., CONNER, G. H. and RILEY, W. F. **Synthetic media powder to enhance rumen microfloral growth and activity: preliminary report.** *Vet. Med.*, 1953, **48**, 349-350. [East Lansing, Mich.]

The use of a synthetic rumen medium, "Profloran", of unstated constitution in the treatment of disorders of the rumen of cattle is described. The 139 cases treated are classified as traumatic gastritis, stasis and putrefaction in the rumen, impaction of the rumen, and inhibition of rumen flora by overdosing with molasses, sugars or sulphonamides.

All animals, except those in the last category, were subjected to laparotomy in order to remove foreign bodies or rumen contents. In some analyses fresh rumen contents from a donor animal were administered. "Profloran" was given to all animals and the opinion is expressed [with no objective data to support it] that in the 130 survivors recovery was more rapid than could have been expected without the administration of this material.—A. T. Phillipson.

1396

GÖTZE, R., AEHNELT, E. and FREESE, U. **Zur Methionintherapie bei Stoffwechsel- und Leber-Erkrankungen des Rindes.** [Methionine therapy of metabolic and liver disorders of cattle.] *Berl. Münch. tierärztl. Wochenschr.*, 1953, **66**, 219-222. [Klin. Geburtsh., Tierärztl. Hochsch., Hanover.] English summary.

Methionine by injection has been used in many widely different diseases of cattle and good results are claimed, explicable on the basis that, even when it has no direct effect, it protects the liver cells from damage.—I. Leitch.

1397

COLBORN, L. R. **Free fatty acids and rancidity in poultry feeding-stuffs.** *Vet. Rec.*, 1953, **65**, 579-580. [Nairobi, Kenya.]

It is suggested that heavy losses of chicks are caused by mashes containing rancid fats. Post-mortem examination reveals no conclusive signs, but there is generally evidence of acute digestive disturbance.

A survey of common constituents of mashes showed that rancidity, indicated by a high content of free fatty acids, developed readily, especially in products stored for several months, in Nairobi, where the mean temperature for the year often reaches 70° F. Attention to conditions of storage and rotation of stocks is recommended.

DEFICIENCY DISEASES

1398

STRUCK, M. **Die häufig bei Schlachtschweinen beobachteten pathologischen Leberveränderungen sind auf Eiweissmangel (Fütterungsfehler) zurückzuführen. [Pathological changes frequently seen in liver of pigs at slaughter are referable to protein deficiency (malnutrition).]** *Berl. Münch. tierärztl. Wochenschr.*, 1953, **66**, 257-259. [Zentralschlachthof, Hamburg.] English summary.

Veterinary inspectors are familiar with pathological livers in pigs at slaughter, showing all degrees of change from incipient hepatitis to advanced cirrhosis. On the basis of work with other animals and man, these are attributed to protein deficiency, especially deficiency of sulphur amino-acids.—I. Leitch.

1399

STEWART, J. **The effects of cobalt deficiency on the appetite of lambs.** *Brit. J. Nutrition*, 1953, **7**, 231-235. [Moredun Inst., Gilmerton, Edinburgh 9.]

Four sets of paired lambs were given a cobalt-deficient ration. One of each pair received a supplement of 10 mg. Co weekly but feed intake was restricted each day to the amount eaten by

N.A. and R., January 1954

the other member of the pair on the previous day. Each pair of lambs made almost the same weight gains and gained much less than control lambs given Co and fed to appetite.—F. C. Aitken.

1400

KEENER, H. A., PERCIVAL, G. P. and MORROW, K. S. **Cobalt treatment of a nutritional disease in New Hampshire dairy cattle. A preliminary report.** *Univ. New Hampshire Agric. Exp. Stat. Circular* 68, September 1944, pp. 8. [Durham, N.H.]

This reports the progress of the first year of investigation of a wasting disease of cattle prevalent in Carroll County, known locally as "Burtonail". Cobalt treatment of a number of cases met with remarkable success; there was immediate improvement in appetite, followed by great improvement in condition. For prevention or cure of slight cases a mixture of $\frac{1}{2}$ oz. Co sulphate with 100 lb. salt is recommended. For severe cases a dilution of 1 oz. Co sulphate in 1 gal. of water is recommended, mature animals being given 1 tablespoonful daily or 3 tablespoonfuls twice weekly for one or two weeks and then given access to the salt-cobalt mixture. Calves severely affected should be given 2 teaspoonfuls daily or 6 teaspoonfuls twice weekly for the first 2 weeks, followed by 1 teaspoonful daily until the animal is old enough to eat the salt-cobalt mixture.

PÁLSSON, P. A. and GRÍMSSON, H. **Demyelination in lambs from ewes which feed on seaweeds.** *Proc. Soc. Exp. Biol. Med.*, 1953, 83, 518-520. [Inst. Exp. Pathol., Univ. Iceland, Keldur, Reykjavik.]

Incoordination of movement characterises a disorder in lambs of ewes feeding on seaweed in late pregnancy. Demyelination confined to the cerebrum was found. Cu intake was adequate, but blood Cu in ewes from affected areas was only 0.2 compared with 1.0 mg. per litre in blood of ewes from unaffected areas. The Cu content of oven-dried livers of affected lambs was 7 p.p.m. compared with 140 to 210 p.p.m. in lambs from unaffected areas. A Cu supplement given to the pregnant ewes largely prevented the disorder.

POISONS OCCURRING IN FOOD

1408

HARVEY, J. M. **Chronic endemic fluorosis of Merino sheep in Queensland.** *Queensland J. Agric. Sci.*, 1952, 9, 47-141. [Biochem. Sect., Chem. Lab., Div. Plant Indust.]

The indirect effects of chronic endemic fluorosis in certain areas in Queensland present a serious problem. The literature on fluorosis is reviewed and the distribution of fluoride waters where endemic fluorosis occurs is indicated and the areas are described. There is no district where the water contains more than 10 p.p.m. F.

Experiments were made with Merino ewes drinking water with 5 or 10 p.p.m. F. There was no increase in the F content of the milk, and no evidence that the high intake by the ewe was reflected in a high level in the foetus, so that

maintenance of the ewe in these areas could not have a harmful effect on the suckling lamb. Fleece weight and quality are affected only indirectly by fluorosis when the animals cannot graze properly because of bad teeth, and under the experimental conditions reported, when the feed was chaffed, in contrast to the normal somewhat coarse pasture, no effect of high F intake on the fleece was observed after 2 years. Storage of F in the edible portions of the carcass was not sufficient to constitute any danger to man. The effects of diets high in protein, Ca or P were investigated but, contrary to results obtained by other workers with laboratory animals, they had no mitigating effect on the development of fluorosis.

No practical method of removing fluoride from the waters under investigation was found, and the only advice is that management must play a major part in the elimination of chronic endemic fluorosis. Since it is during early life that the ill effects of high F intake are most marked, young sheep should be given water with a comparatively low F content, i.e., surface waters or supplies from as near the borehole as possible. The pasture along the irrigation channels has a high F content, and this must be kept in mind in managing the stock and changing grazing areas.

The teeth and bone lesions associated with fluorosis in Merinos are described and illustrated, but the latter do not agree with the reports of other workers, rarefaction rather than thickening of the mandibles and long bones being observed.

CUNNINGHAM, H. M., BROWN, J. M. and EDIE, A. E. Molybdenum poisoning of cattle in the Swan River Valley of Manitoba. *Canad. J. Agric. Sci.*, 1953, **33**, 254-260. [Dept. Animal Husb., Cornell Univ. Agric. Exp. Stat., Ithaca, N.Y.]

Signs of molybdenum poisoning similar to those reported by Ferguson *et al.* (Abst. 2240, Vol. 10) have been found in cattle grazing in the Swan River Valley. The herbage was found to contain up to 25.6 p.p.m. Mo as compared with 1.9 p.p.m. in the herbage of similar areas nearby where the trouble did not occur. The toxicity was overcome by administering 2 g. Cu sulphate daily as a drench or a salt lick. Administration of Co as sulphate was of no benefit. The disorder was produced experimentally in cattle by drenching with ammonium molybdate, but considerably more Mo than was found in the toxic forage was required to induce the disorder in cattle fed indoors. There was some evidence that cows may transmit the disorder through their milk to calves but it appeared that the cow was soon able to build up a resistance to the passage of ingested Mo into the milk.—W. Godden.

Of 103 day-old chicks fed on a chick mash containing trichloroethylene-extracted soya bean oilmeal 27 died within 49 days. Of a similar number of controls given hexane-extracted meal only 5 died. Among the survivors, susceptibility to pseudomonas, pasteurella and coccidiosis infection was greater in those receiving the trichloroethylene-extracted meal.—J. S. Thomson.

IMMUNITY

1416

STEWART, D. F. and GORDON, H. M. **Studies on resistance of sheep to infestation with *Haemonchus contortus* and *Trichostrongylus* spp. and on the immunological reactions of sheep exposed to infestation. 6. The influence of age and nutrition on resistance to *Trichostrongylus colubriformis*.** *Austral. J. Agric. Res.*, 1953, 4, 340-348. [Div. Animal Health and Prod., C.S.I.R.O., McMaster Animal Health Lab., Sydney.]

The influences of age, nutrition and previous infestation on the resistance and antibody response of sheep artificially infested with *Trichostrongylus colubriformis* were studied. Resistance was measured by egg counts and the circulating antibody level was measured by the complement fixation method.

In the first experiment 3- and 4-year-old sheep which had been kept worm-free since birth were dosed with *T. colubriformis* larvae; no difference in resistance or antibody response between these age groups was found.

In the second experiment 48 nine-month-old lambs which had been exposed to infestations in the field were brought in and dosed with phenothiazine. They were divided into 3 dietary groups; high-protein, starch equivalent 53 per 100 lb., total protein 20 per cent.; normal, S.E. 56, T.P. 10, and poor, S.E. 34, T.P. 6. The sheep were dosed with *T. colubriformis* larvae after 3 months on this diet. Eight of the 16 on the poor diet developed heavy infestation, compared with 2 in each of the other 2 groups. Diet did not greatly affect the antibody response. Ten sheep on the poor diet and 14 on each of the other 2 diets developed similar levels of circulating antibodies. Twelve of the sheep on the poor diet were

given a further challenge dose of 200,000 larvae, which they all resisted except one. Thus the continued low diet did not appear to lower the resistance of sheep which had had previous infestations of *T. colubriformis*.

In order to test whether nutrition had an important effect on the response of sheep to their first infestation, a similar experiment was made with lambs which had been born and reared in a worm-free environment. Only 2 dietary groups were used, high-protein and poor. The lambs were infected when 8 to 9 months old, after 10 weeks on the experimental diets, and both groups developed infestations. The egg counts were slightly higher and persisted a little longer in the poorly-fed group. Six on the high-protein diet and 7 on the poor diet showed serological responses. These lambs resisted further doses of larvae given 5 months after the initial infestation.—G. C. Hunter.

1417

PRICE, D. A., HARDY, W. T. and BOUGHTON, I. B. **Phenothiazine-salt mixture for control of *Haemonchus contortus* in range sheep.** *J. Amer. Vet. Med. Assoc.*, 1953, 123, 132-135. [Sonora, Tex.]

The use of a 1:9 phenothiazine-salt mixture as an alternative to drenching for controlling *Haemonchus contortus* in range sheep was tested over a period of 7 years. The ewes and their lambs had free access to the mixture; the controls, in a similar adjoining pasture, were supplied with white salt only. Observations were made on egg counts, worm counts at autopsy and larval development. The data collected seemed to show that the phenothiazine-salt mixture controlled *H. contortus* satisfactorily throughout the period of the experiment.—G. C. Hunter.

SEXTON, W. A. **Chemical constitution and biological activity.** E. and F. N. Spon, Ltd., 22 Henrietta St., London, 1953, 2nd revised ed., pp. xxiii + 424. Price 60s.

In the review (Abst. 1262, Vol. 20) of the first edition of this valuable book the hope was expressed that supplements or new editions would appear regularly "to keep the reader abreast of the very rapid advance of the subject". Now, after only 4 years, the author has fulfilled this hope. The need for a new edition as a result of advances in knowledge is clearly indicated by the fact that considerable alterations have been made in 5 chapters; a further chapter, that dealing

with insecticides and anthelmintics, has been extended and revised as a whole; the chapters on cancer and plant growth regulators have been rewritten. The tribute paid earlier to the author and the first edition is equally applicable to the present edition. It is excellently produced and well supplied with references to the literature and has an adequate subject index.—W. Godden.

MASSINGHAM, H. J. and HYAMS, E. **Prophecy of famine. A warning and the remedy.** Thames and Hudson, London, 1953, pp. 192. Price 12s. 6d.

It is the authors' considered opinion that Britain will not be able to go on importing about half her food. Countries from which food supplies are obtained will either cease to have exportable surpluses or will no longer require the manufactured goods which Britain now sells to pay for imports of food. There is also the possibility of war cutting off supplies even before the first two situations materialise. In short, Britain will starve, and that quite soon. This thesis is developed in Chapter 1 by Mr. Hyams. In the second chapter he gives data on imports and sources of supply. The third chapter, entitled "The Abuse of Land", shows some of the reasons for such dependence on imports; the diversion of agricultural land to other uses such as housing, industrial purposes, sport, roads is deplored and the conifer policy of the Forestry Commission is criticised as unecological. This chapter by Mr. Massingham is followed by some of Mr. Hyams's ideas on how the gap between requirements and present home production could be narrowed by changes in agricultural policy. These include the ploughing up of much permanent pasture to increase cereal production, the reclamation of rough grazing for beef animals, and the cutting of

liquid milk consumption by half to increase supplies of butter, cheese and incidentally bacon. At this point one becomes doubtful of the soundness of Mr. Hyams's nutritional basis for his planning, when he says on page 79 "Milk is, of course, a perfect food for infants, but the digestion of an infant differs from that of an adult, and raw milk for all above the infant age is not particularly easy to digest", and further, "most children dislike milk and much of that forced on the poor creatures is wasted". Such doubts harden into certainty when one reads on page 90 that according to Mr. Hyams vitamins A and D are plentiful in blackcurrants, apples and oranges and that Mr. Hyams would substitute home-produced blackcurrant juice and apple juice for orange juice as a welfare food. Even if a slip of the pen accounted for Mr. Hyams writing vitamins A and D instead of vitamin C we have yet to account for his error in thinking apple juice is a good source of vitamin C.

In the fifth chapter Mr. Massingham again takes up the subject of the use of land and describes how land may be used to better advantage. This leads him to his main conclusion that Britain can only use her land to the best advantage by becoming a nation of peasant farmers. Only in this way can the land be used efficiently enough for Britain to become self-supporting. This theme is developed in Chapter 6. Mr. Massingham's contribution to the book ends with Chapter 8 entitled "A Self-supporting Soil", in which he discusses the building up of soil fertility, especially with organic material compost, sewage sludge and the like.

Mr. Massingham died before the remaining Chapters 7 and 9 were written by Mr. Hyams. In these, land nationalisation is advocated as a means of establishing a modern peasantry, the state to act as did the good lord of the manor in earlier peasant communities. Mr. Massingham's wife in a preface dissociates her late husband from such a political solution. Be that as it may, the authors were agreed that Britain could feed her population only by becoming a nation of small peasant farmers and suggest that by suitable education the people could become such a peasant population.—F. C. Aitken.

HARRIS, C. F. **Handbook of dietetics for nurses.** Baillière, Tindall and Cox, 7-8 Henrietta St., London, 1953, pp. xv + 196. Price 17s. 6d.

The author, who is chief therapeutic dietitian at University College Hospital, has aimed at emphasising the connection between good health and correct feeding, and the first half of her book is appropriately devoted to the nutrition of the healthy. At the outset the functions of individual

nutrients and the basic facts on digestion and absorption are recounted briefly; in places the treatment is scrappy, *e.g.*, that of the more recently recognised B vitamins. Next come energy and nutrient requirements in health, with tables of the U.S. and British Medical Association recommended allowances and a nomogram for calculating individual energy requirement from height, weight, age and sex. The characteristics of common foods and the effects of cooking on them are discussed in detail; a table of nutrients supplied by common foods per oz. edible portion is included. Chapters follow on diet in pregnancy and lactation and on the feeding of infants, including premature infants, and young children, with specimen diets.

The second half of the book opens with a description of the principal deficiency states, with photographic illustrations. The remaining chapters deal with special diets for diseases of the alimentary tract, liver and kidneys, cardiovascular disorders, rheumatic disorders, gout, diabetes, obesity, leanness and starvation, and some other conditions. All these are explained in detail, with specimen diets and lists of suitable foods and foods to be avoided.

The book is very clearly printed and opens flat.
W. M. Deans.

BRANDLY, C. A. and JUNGHER, E. L. (Eds.) **Advances in veterinary science. Volume 1.** Academic Books, Ltd., London, 1953, pp. xi + 431. Price \$9.

This volume forms the first of a series designed to review progress in veterinary research and the practical application of new veterinary knowledge. Information is offered under 8 chief headings, each with separate authors, but it is disappointing to find that the selection and arrangement of these main sections has resulted in considerable overlapping and repetition. These faults are par-

ticularly noticeable in the chapters on animal diseases and human welfare, and veterinary public health.

In some instances, too, the subject matter leaves much to be desired. Some of the advances described can in no sense be considered recent, and much recent work published in countries other than the United States is totally ignored. Indeed, despite the appointment of a distinguished and international Advisory Board, there is a distinct American bias throughout the whole work. Bovine tuberculosis, for instance, which has for long been a serious scourge in almost every country in the world except the United States, is dismissed in little over a page. By contrast, however, work on bovine mastitis, the antibiotics and the sulphonamides is very capably and fully reviewed. Other chapters deal with virus diseases, diseases of pigs and infertility in cattle.

There is little in this first volume of direct interest to the specialist in animal nutrition, apart from a discussion of "yellow fat" disease in pigs and a review of the part played by nutrition in bovine infertility. A comprehensive review of this latter subject is badly needed to-day, but unfortunately the subject is very incompletely covered. Only one reference is quoted in regard to the part played by trace minerals in reproduction, and only two to the possible influence of phosphorus deficiency; consequently these receive a disproportionate amount of attention and the picture presented is unbalanced.

No doubt in a volume of this broad scope superficial treatment of many important points is inevitable. It is not claimed, of course, that the reviews are exhaustive, but one wonders whether the concept of the series is not too wide and whether it would not have been more useful to have narrowed the horizon and at the same time widened the treatment of individual questions, particularly those involving highly controversial issues. As it is, the approach to many of the subjects considered is too academic for the practitioner and too incomplete for those engaged in research.—W. A. Greig.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Development Paper No. 35. Co-operative hybrid maize tests in European and Mediterranean countries— 1951. Rome, Italy, September 1953, pp. v + 145. Price \$1.50.

Commodity Reports. Fats and Oils No. 5. Rome, Italy, October 1953, pp. 61. Price \$0.25.

Vol. 24, No. 1

On statistics and information available to September 1953 it is concluded that world production per person is now only slightly below pre-war level and that, compared with pre-war, consumption per person has increased substantially in Latin America, Africa and some Asian countries and decreased slightly in Western Europe, United States and Canada. Should there be no major

changes in world economic activity or in international political conditions, the general levels of prices in international markets of fats, oils and oilseeds are expected to remain about the same in 1953 to 1954 as in 1952 to 1953 or to decline only slightly.

Monthly Bulletin of Agricultural Economics and Statistics.

Vol. 2, No. 9, September 1953, pp. 56. Review of current agricultural plans and programs in Latin America. No. 10, October 1953, pp. 48; No. 11, November 1953, pp. 56.

The Work of FAO, 1952-53. Report of the Director-General. Rome, Italy, October 1953, pp. 46. Price \$1.00.

The Director-General recalls how, soon after its foundation in 1945, FAO, the first of the "action agencies" of United Nations, was confronted with the problem of food shortages. With the passing of these its activities can now be grouped in two categories, the provision of an intelligence service to Member Nations and the framing of programmes to supplement those initiated by governments. The present report refers to the many ways in which the Organization has implemented these. In animal nutrition, deficiencies of P in Mexico and of I in Ecuador have been reported and in human nutrition especial interest has been taken in the composition of foods and the protein nutrition of children. In its aiding activities in animal nutrition, pasture management and national feeding resources were discussed at meetings in America and France. In human nutrition, supplementary feeding experiments were made in Belgian Congo and French Equatorial Africa with skimmed milk and, in other countries where increased milk supplies are not readily available, with soya bean products in Asia and refined fishmeal in South America. A final section summarises the Organization's informational and educational services.

Activities of FAO under the Expanded Technical Assistance Program. 1952-53. Rome, Italy, October 1953, pp. 88. Price \$1.00.

A summary is given of the investigations made since the Program was approved by the General Assembly in December 1949. In three years more than 2000 experts have assisted in the economic development of 82 countries and territories. This picture of their achievements has a regional background.

Agriculture in Asia and the Far East. Development and Outlook. Part 1. Report of the FAO Regional Meeting on food and agricultural programs and outlook in Asia and the Far East, held in Bangalore, State of Mysore, India, 27 July-5 August 1953. Part 2. Working paper prepared by FAO for discussion at the Regional Meeting and revised in the light of additional information furnished at the Meeting. Rome, Italy, September 1953, mimeographed, pp. iv + 221, n.p.

Asia and the Far East as a region provides the "hard core of the world's food problem" and to the conference there came, for the first time, ministers and policy-makers of the governments of the region. Their report and 10 resolutions are published in full.

The working paper which in its revised form will be the basis, for that part of the world, of the review at the 7th Session of the FAO Conference, gives a detailed analysis of the food shortages and of targets and estimates of agricultural and livestock production and improvement. Reference is made also to fisheries development and to problems in forestry and the use of forest products. Although the prospects in most of the territories are of a rise in production which will result in more calories being available in 1956 to 1957 there are indications in others, notably Ceylon, that current levels may not be attained. Qualitative deficiencies as, for example, in protein call for increased milk production or, if this be not feasible, for development of fisheries or in production of cheaper protective foods of vegetable origin. The question of animal feeding is a critical problem and the heavy pressure of human and livestock populations on land resources will require the integration of both if the production of feedingstuffs for animals is not to conflict with that of human food.

Prospects for agricultural development in Latin America. Rome, Italy, n.d., mimeographed, pp. v + 146. Price \$1.00.

This publication reviews developments in relation to the discussions which took place at the FAO Latin-American Regional Meeting on Food and Agricultural Programmes and Outlook held in Montevideo in 1950 and to the production targets and estimates for the year 1956-57.

The plans and programmes of the individual states are reviewed. Of the expansion schemes those in irrigation may make some contribution towards attaining objectives but the parts to be played by colonisation, improved soil management, use of fertilizers and schemes for plant protection are likely to be small. Greater efforts will be required from governments in schemes for seed and livestock improvement and for extension services. Mechanisation has made great strides but for many years the basic problem will be that of supplying power-operated equipment to small and medium-sized farms. Development of fisheries has been checked by high prices and by the indifference of consumers who prefer meat and poultry but there seems no reason why targets should not be reached. Of the economic measures price policy is beyond control by being dependent on international agreement but farm credit schemes with capital, which, it appears, will have to come from domestic sources, could contribute largely to the solution of the problems of agricultural expansion.

FAO Fisheries Bulletin. Vol. 6, No. 5, September-October 1953, Rome, Italy. Price 30 cents, pp. 159-193. Improving the fisheries contribution to world food supplies.

The relation of the production during 1950 to 1952 to pre-war level and to the 1960 target of the Second World Food Survey is considered. Present production is mainly from waters adjacent to land masses in the Northern Hemisphere. The 6 major producing countries of the world produce 61 per cent. of the world's total production for the period and there was evidence that, in the last 40 years, they have more than doubled their catches. Increased production has in some areas, e.g., Europe and North America, resulted from advances which have

N.A. and R., January 1954

solved the problems of distance while in others, *e.g.*, Japan and Norway, it has followed the more complete exploitation of coastal resources.

The bases of possible expansion are considered in detail with special reference to increased productivity and the technical requirements for its realisation and an appraisal of their possible effects leads to the conclusion that the world's aquatic resources could yield much greater quantities of human food than they do at present.

Deterrents do, however, exist in the form of certain weaknesses in the economic system as it concerns the producers, in an ineffective demand and in the lack of organisation and finance in the industry. These and other conditions which have a limiting effect on developments are dealt with fully.

INTRODUCTION

IN the Foreword to a recent posthumous publication on the growth of children from birth to five years of age (Low, 1952) it is stated that "Professor Low profoundly disagreed with the current statement that children of today are taller and heavier. He maintained that, however excellent the nourishment received by certain children, they would not grow beyond the size of their type, and he was convinced that even if food was poor, provided a child got sufficient it would reach the stature for its particular stock." In vivid contrast to this we have the fact quoted in the Report of the Chief Medical Officer of the Ministry of Education for the years 1948 and 1949 (1952) that the mean height of 5-year-old boys in Wolverhampton rose by more than 4.5 inches and of girls by more than 6.5 inches between 1909 and 1949, and the analyses of secular changes in height and weight of schoolchildren in London by Menzies (1940) and Daley (1950), in Glasgow by Campbell and Weir (1948) and for several areas by Clements (1953), all showing substantial in-

creases at all ages since records were regularly made. Professor Low was no doubt right in his conviction that the maximum height to which any individual can attain is fixed by type, stock, or heredity, but it is equally sure that over the last 100 years a very high proportion of children in Britain were debarrred by disease and deformity from coming near to their potential upper limit. There are few who would deny now that the speed of growth has increased in parallel with the great improvements that have been made in hygiene, housing, medical care, diet and standard of living in general. It is still debated whether or not the increase in speed has meant increase in adult stature or merely earlier maturity. *A priori* it might be argued that, as the thousands of sick and crippled children of last century and the beginning of this century have been replaced, as they certainly have been, by well and progressively bigger children, the mean height of adults must have increased. American literature confidently reported increases in attained height of particular groups of population, even of high social class such as Harvard students (Shuttleworth, 1951). Danish

anthropologists kept track of the height of recruits and it is now taken for granted that there has been a general increase in height of the Danish population. It was therefore unexpected and disturbing when Morant in 1950, as part of a symposium on growth, read a paper to the Royal Society in which he presented an analysis of all the data he could assemble on height of British men and deduced that maximum mean height is attained earlier but is not greater than it was a hundred years ago, and that the price of earlier attainment is earlier decline. The contrast was so striking that we decided to re-examine the original reports.

THE MEANING OF MAXIMUM HEIGHT

The term maximum height covers two separate concepts and it is important to make and keep a clear distinction between them.

In the Individual

In the individual, growth in height continues, health and food permitting, certainly until the epiphyses of the long bones unite, but probably very little thereafter. According to older textbooks of anatomy, fusion of the epiphyses of the femur occurs at age 20. There must, as with any other biological end-point, be a distribution about a mean age of fusion, but whether age 20 is intended as a mean or as an upper limit does not appear. From the general nature of the material used for such studies, it is likely that age 20 would approximate to the upper limit for epiphyseal union in non-pathological subjects. According to Todd (1930) that estimate derives from the middle of last century and an extensive study under his direction gives 17.0 and 18.5 years as limits for epiphyseal union in boys for the femur, including both epiphyses, and the same limits for girls; for the tibia and fibula (distal only) 15.5 and 16.5 years for boys and a year earlier for girls.

That being so, it seems unlikely that much true growth would occur after age 20 at any time in the past century, and possible that any increase in measured standing height discovered within a few years after 20 could be caused by change in posture, the correction of a stoop, or merely improved tone of muscle or expansion of intervertebral discs induced by physical training (*cf.* below, Reid's students).

What happens to the individual later in life has not been studied and is a matter of "common knowledge" only. There is a vague general impression that, apart from the development of occupational stoop or other similar disability, there is little change until some undefined age usually placed anywhere between 50 and 65. The

age, the cause and the rate of shrinkage are all unknown.

In a Population

The application of statistical methods to the study of mortality and problems of public health in the beginning of last century had a natural sequel in the beginnings of the statistical study of man himself. William Farr was chairman of the Anthropometric Committee of the British Association from 1875 to 1879 and was succeeded by Francis Galton. The emphasis shifted from study of the individual to study of the group, with a tendency to treat data as if validity necessarily increased with the size of the group studied. The relatively recent application of statistics to biological and medical problems has brought a new awareness of the importance of study of the individual.

The mean maximum height of a sample of men, as estimated in practice from data grouped by age in some arbitrary fashion, may be defined as the mean height of all the men in the age-group which shows the greatest mean height, and the age of attaining mean maximum height as the mean age of the youngest age group to reach it. Other methods have been used (Morant, 1950). Mean maximum height may then be quite different from the mean adult height as will be apparent from the distribution of heights by age after age 20, as discussed and illustrated below.

The curve representing the distribution of heights by age after age 20 is a composite, varying with the nature of the samples used and subject to modification by a continuous process of weeding-out by death as age advances. When anthropometric records began over 100 years ago general mortality rates were very high. For details see Simon (1897) pp. 288 *et seq.* and the Registrar-General's Reports which he cites. Mortality in general improved steadily with improvement in economic conditions and, up to the end of the century, there was improvement in all age groups except the oldest and youngest. The youngest improved rapidly in the present century (Greenwood, 1936). Even now a social class gradient persists, greatly modified. There has also been throughout the last 100 years a social gradient in both rate of growth and attained maximum height. It follows that the older the sub-group of population measured, the more it will tend to represent the better-off and better-grown of the people born within the corresponding sub-period of the past century. Throughout the same time both expectation of life and attained height have been greater for rural than for urban populations.

Morant (1950) talks of maximum mean height but appears to operate only with the means of maxima of samples from different classes of the

population to give mean maximum height. There will probably be little difference in practice but the term maximum mean height implies a refinement of analysis which the data can ill carry.

DESCRIPTION OF THE RECORDS

The ideal material for a study of secular change in growth and maximum height of the population would be obtained from repeated measurements of samples of the whole population taken at intervals over the whole of life for the period under investigation. Instead of this, for adults we have no more than a limited number of cross-sectional samples of restricted and often undefined sections of the population at scattered intervals. The only investigation which recorded repeated measurements on a very small number of the same individuals recorded only weight (Kemsley, 1953). The position is much better for growth of school-children for whom periodic measurements since the School Medical Service began constitute an impressive series of partial replacement samples, but, so far, our assembly and analysis of these have not gone further than to confirm for Council school children the secular increase in rate of growth and in height attained at a given age.

Last Century

Among the earliest systematic works on anthropometry is that of Quetelet (1870) spanning the years from 1832 to 1870. His data were mostly of Belgian origin but he did handle some British. He was of the opinion that individuals of both sexes maintained their maximum height until the age of 50 years and by the age of 90 had lost 3 inches (wrongly quoted by Roberts as $1\frac{1}{2}$). As an illustration of the long standing of some "modern" views on growth, the following remarks by Quetelet in Roberts's translation are of interest. "In considering a particular individual, his growth is far from being as regular as that indicated in the tables. There are nearly always points at which the development of a person is arrested, as also there are times of growth more or less rapid. These anomalies are observed about the age of puberty and after illness. . . . When we look on a great number of persons these little anomalies disappear in the general means, and what is wanting in the development of one is compensated for by an excess of growth in another." The modern counterpart of this very cautious statement might be Tanner's (1951) assessment of the relative statistical value of cross-sectional, partly longitudinal or partial replacement, and purely longitudinal studies. Morant (1951) gives a brief chronological review of British data.

The influence of Quetelet can be seen in the work of Beddoe (1870) and Roberts (1878). Beddoe should receive homage as the first to make a major attempt at measuring the adult male population of these islands. The age limits he set, guided, he said, by Quetelet and others, were 23 years to 50 years of age on the assumption that maximum stature had been attained on the average by 23 years of age, and that people aged from 23 to 50 all had the same average height. Beddoe himself had the impression that a decrease began rather before than after fifty but conceded that his impression might have been biased by hospital experience. His records came from four sources: (1) private returns, mostly from rural doctors, (2) records of heights of criminals, (3) returns from most county asylums, and (4) returns of volunteers for the army for two years during which the qualifying height was 65 inches.

In his paper (1870) the data from the first three sources are presented at length, and the military data are classified by occupations and subdivided regionally.

He was aware of the difficulties to be met in the effort to obtain a fair sample of the population or of a particular class, but believed that his private returns, with a few exceptions, succeeded in doing this. On the question of accuracy of the measurements he stated that "one man is content with less exactitude in these matters than another", but no mention was made of his own omission to give specific directions for measuring stature.

Of the data for recruits he has to say that, within regions, differences in stature existed between different occupations. These differences, he says, "are in truth vastly less than they would have been, had there been no minimum standard. It is obvious that the lower the average stature in any trade, the greater will be the proportion of its members who will be shut out from the comparison, and the greater will be the difference between the true average height, and that yielded by those men who are tall enough to enter the army." When the recruits were separated into indoor and outdoor workers, the outdoor were the taller by 0.8 inch, a difference which, Beddoe surmised, might represent an average difference of more than 2 inches between the populations from which these samples were drawn.

Beddoe surveyed the private returns in geographical order, and confirmed or corrected their indications against those of the other three sources of returns. He found fairly general agreement between sources (1), (2), and (3), but the recruiting returns were often at variance with them. "What may be the average stature of adult Englishmen is a matter of speculation and curiosity, on which one cannot give any but a cautious and guarded opinion. Without doubt it lies somewhere between

5 feet 6 inches and 5 feet 7 inches (1.676 and 1.702 metres). The mean of my private returns (excluding those which consist mainly or wholly of picked men) would occur somewhere about 5 feet 6½ inches (1.693 metres); but the number of those reports whose average greatly exceeds this mean is greater than that of those whose average falls greatly below it. . . . On the whole, my estimate would be 5 feet 6.6 inches or 1.690 metres.

The average for Scotland must certainly be very much higher, perhaps as high as 5 feet 7½ inches; but this can be little better than a mere guess."

Beddoe and others found that stature in general was greater in rural than in urban districts. It is not possible in all of his private returns to separate into urban and rural categories, but since most of his "allies" were country doctors, it would appear that the greater proportion was rural. According to the census of 1871, 62 per cent. of the population of England and Wales was urban and the proportion in Scotland was approximately the same, so that it is likely that the estimates for both countries were biased upwards.

Roberts (1878) was a pioneer of anthropometric technique. In his book he produced, as a guide to measurements, a chart which he hoped would be used generally, and his accumulation of data was secondary to the construction of his chart. He expressed the need for world-wide inquiries to settle "many important and interesting physiological and pathological questions bearing on the growth and development of the body"; he felt that nation-wide surveys would help us to "recognise the nature and peculiar effects of various influences at work in modifying the physical development of our labouring population". There are, in addition, some interesting sets of data in this manual. Among them is a table showing the heights, at different ages, of samples of the "most favoured" class* of the English population, and another similar table for samples of the artisan class from large English towns. The table for the artisan class indicates that maximum stature was attained at 22 or after and was about 66.7 inches. A third table presents data from the two described above with some additional data. It appears less reliable, because the data taken from the first table had been revised, or altered in transcription, and data for recruits include two series that are not strictly comparable. Those taken from Beddoe are used uncritically without regard to Beddoe's conclusions concerning them, and the earlier series (1862-63) refer to two years in which the qualifying

height was 66 inches, an inch more than for Beddoe's recruits.

Nearest in time to these are the results of the British Association Anthropometric Committee survey (1881-1883) and data for the males measured by Galton (1885) in his First Anthropometric Laboratory set up at the International Health Exhibition in South Kensington in 1884. There is little doubt that Galton's measurements would have been most carefully made, but on the other hand it would be extremely difficult to decide what population they represented. The subjects were predominantly from the south of England, interested in the Exhibition, and willing and able to pay for admission. We know no more than that.

The Report by the British Association was based in the main on the data assembled by Beddoe and Roberts. Two analyses were made, one by social class and the other by region, so that it was not possible to decide the extent to which regional differences were attributable to social class differences and vice versa.

On the attainment of full stature the Report says: "The Tables do not show distinctly at what period man attains his full stature, and much difference of opinion exists on this subject. Some French writers (Barnard, Allaire, etc.) maintain that growth in height goes on until the 32nd or 35th year, and Dr. Baxter arrives at the same conclusion from the statistics of the United States Army; while most English writers (Danson, Aitken, Roberts, etc.) regard the 25th as the year of mature growth, and Dr. Beddoe places it as early as the 23rd year, admitting, however, that a slight increase may take place after this age, . . . it is probable that little actual growth takes place after the age of 21, and that it entirely ceases by the 25th year. It is evident, moreover, . . . that the full stature is attained earlier in the well-fed and most favoured class (Class I) than in the ill-fed and least favoured classes of the community (Class IV)." It was found also that stature did not alter with advancing age, and on this the Report may be quoted: "The maintenance of the stature throughout life . . . is a new and unexpected fact, but it is probably due to the survival of the taller and better developed members of the population, and the elimination by disease or death of the smaller and feebler ones. Quetelet has stated that man attains his maximum height at the age of 30 years, and maintains it up to 50 years, after which it begins to recede, and at 90 it has lost three inches. This may be, and probably is, true of individuals if measured from year to year, but it does not appear to be true of the population in the aggregate. The loss of stature resulting from the degeneration and loss of tissue, and the stooping position assumed by old people, is more than counterbalanced by the survival of a

* The "most favoured" class must correspond roughly with Class I of the Registrar-General's (1938) occupational classification as used in his Decennial Supplements on Occupational Mortality. The parallel between other classes in the two series is not so clear.

greater number of individuals who are above the average in height."* It was suggested that much of the confusion arose from the "faulty method of relying on the measurements of many different individuals, instead of measuring the same individuals from year to year until growth ceases".

The word "or" in the phrase "disease or death" may be unintentional but it contains an important truth, for in these older series the sick and the crippled were not measured, but only those who were out and about.

There are several different estimates of adult stature in the British Association Report. One set of estimates (p. 258), made from the whole adult sample without regard to whether the proportions of the subjects in the different social classes in the sample represented the proportions in which they occurred in the population, was: Scots 68.71 inches, Irish 67.90 inches, English 67.36 inches, Welsh 66.66 inches; overall 67.66 inches. A second estimate, from subjects aged from 25 to 55 years, with allowances for the geographical, but not for the social class distribution (Table IV, p. 265), was 67.58 inches for the United Kingdom. The third estimate given (Table XIV, p. 284) takes account of the social class distribution, but not the geographical. This was based on adults from 25 to 30 years of age and was 67.21 inches. Clements and Pickett (1952) assert that Social Class I was over-represented in this sample.

Although the Anthropometric Committee expressed the view that its work was by no means completed, it may be that the publication of the Report gave anthropologists a feeling of achievement. Whatever the reason, there was very little evidence of interest in anthropometric work in the years between 1883 and the sitting of the Inter-Departmental Committee on Physical Deterioration (1904). This body, whose convocation was in great degree due to national concern over the physique of recruits enlisted or rejected during the emergency of the Boer War, presented to the government in 1904 its three-volume report in which it made several statements relevant to this review. As regards the annual returns on recruits it pointed out that "... the class from which the recruits are derived varies from time to time with the conditions of the labour market. When trade is good and employment plentiful it is only from the lowest stratum of the people that the Army receives its supply of men: when, on the other hand, trade is bad, a better class of recruit is available." Confirmation of this view is found in the striking disparity from year to year of the educational qualifications of recruits as disclosed in

the returns, and the phenomenon is reflected to some degree in the changes that occurred in the qualifying stature (see e.g., para. 9717 in Minutes of Evidence). Evidence was given of the extent of diseases affecting growth, rickets, for example, being widely reported. Of this disease one witness stated that in Leeds, as an instance, the incidence among Gentile children in a poor school was as high as 50 per cent. Foremost amongst the recommendations of the Committee was the pressing need for an anthropometric survey, on the grounds "that no sufficient material (statistical or other) was at present available to warrant any definite conclusions on the question of the physique of the people by comparison with data obtained in past times".

This Century

Between the 1904 Report to which we have referred and 1939, surveys were made only on small sections of the adult community. Among them was work by Reid (1912) on medical students at Aberdeen University. He found that male students were not fully grown at about 19½ years. They were measured a second time four years later when they had gained 0.6 inch and then measured 68.3 inches. Of that sample it may be said that it did not represent the "most favoured" class, for the students of that democratic University came from all classes and from rural as well as urban homes in the north of Scotland. Reid, who was himself Professor of Anatomy, was surprised to find that the late increase in height was mostly in trunk length, not in leg length, which suggests that it was not true growth (see above, p. 256).

Several studies of university students were made between those of Venn (1889) and Grant and Hitchens (1953) but, because of the progressive change in representation of the social classes in university populations, we have not examined them in detail. Reid's study was singled out because it was a longitudinal study and therefore important in relation to age of completion of growth in height.

In 1920 the Ministry of National Service published its famous "C3" report with the claim that it was based on a true sample of the manhood of military age, a claim which was not generally accepted. While the controversy still raged, Tocher (1924) published the results of an investigation on Scottish soldiers, measured in 1915 and 1916; in them maximum mean height was about 67.5 inches and was attained between 22 and 23 years of age. There is some question that the men may have been, at least in part, selected by stature so that the regional differences shown, with the Renfrew, Ayr and Lanark group shortest at 66.9 inches, and the north tallest at 68.7, may,

* What Quetelet said (p. 178) was: "On peut considérer la croissance comme entièrement terminée à 30 ans; cependant l'augmentation qu'elle reçoit, après 23 à 25 ans, est déjà à peine sensible."

on the reasoning applied by Beddoe to his recruits, be underestimates of the true regional differences.

In 1935 the Industrial Health Research Board (Cathcart, Hughes and Chalmers, 1935) published its report on "The Physique of Man in Industry". The board used the occupation grouping set out in the 1921 Census of England and Wales and attempted to sample each group adequately over a wide age range, and, except where some industries were geographically highly localised, over as wide an area of the country as possible. A group of undergraduates and one of unemployed males were included also. The report claims success in those aims for all but the group of agricultural workers, which was composed of such small, scattered units that it proved very difficult to sample them. It might with fairness be claimed that the result was a survey of the urban population of the country. The maximum height attained by each of the groups measured was: students 68.9 inches, employed men 67.3 inches, unemployed men 66.5 inches, and the ages of attainment were between 21 and 25. If we apply the proportions in which these groups occurred in the 1931 Census (taking the students to represent Social Class 1) we obtain a weighted mean maximum height for urban Britain of 67.3 inches. Allowing for the advantage in stature possessed by rural over urban subjects, we may consider this an underestimate for the population of the whole country.

Under the Military Training Act of 1939 some 90,000 young men between the ages of 20 and 21, the militiamen called up before the outbreak of war, were medically examined in that year. The results were presented by Martin in 1949. They represent the first set of measurements which can be said to have covered the country as a whole, and the only doubt is whether all the subjects measured had completed their growth, or apparent growth.

From the analysis of these measurements it appears that mean height decreased by small but statistically highly significant degrees from rural to urban to County Borough subjects, a result consistent with earlier work. There was a concomitant higher standard of fitness in country men. The order of heights for different areas of the country was changed from that of the 1880s. The British Association Report placed Scots as tallest, English second and Welsh last; the 1939 data for 20-year-old men placed the English as tallest with an average of 67.5 inches, the Welsh next with 67.1 inches, and the Scots last with 67.0 inches. It was further shown that those who had moved from their birthplace (migrants) were on the average 0.3 inch taller than those who had not. These estimates leave plenty of room for speculation. Were the Scots absolutely and relatively shorter in 1939 because the sample came chiefly from the

lowland industrial belt, or because some of the taller descendants of the 1880 population had migrated to England, or emigrated to be lost to the population altogether?

An inquiry was initiated by the Ministry of Food in 1943, primarily to measure bodyweight changes as a continuing check on the adequacy of the national diet. Measurements of stature were included and the results have been reported by Kemsley (1950). The population sampled was the civilian one in 1943, but, as the author pointed out, not all areas were correctly represented. Scotland, for example, was under-represented, and it seems likely from the nature of the survey that most of the Scottish data would have come from the industrial belt between the Clyde and the Forth, in which case the low stature obtained would be in agreement with the earlier findings of Tocher and of Martin.

For this inquiry three groups of males and three groups of females were sampled, employees of large firms and small firms, and miners and housewives. The shapes of the curves relating height to age were so much alike for the groups of one sex (as was pointed out by Kemsley) that they have been combined and the combined unweighted means are given in Figure 1. In the light of these curves, the meaning of Martin's data must be in doubt, since maximum height was not found in the males until between one and two years after the age at which the recruits discussed by Martin were measured.

Kemsley (1950) included in his paper a curve of stature against age based on over 200,000 males measured from 1885 to 1900 in an American medico-actuarial mortality investigation, and published in 1912. This series agreed with the early British series in showing no reduction of mean stature with age and strengthens the view that a true difference exists between the series of last century and this. It is greatly to be regretted that in the continuation of this work (Kemsley, 1953) weight alone was measured when the same 344 subjects were seen at intervals between 1943 and 1950.

During the years 1939 to 1946 some 70 per cent. of the male population of military age were examined by the medical boards of the Ministry of Labour and National Service. Clements and Pickett (1952) report on the findings for stature from a preliminary study of the 1941 records for Scotland.

It is evident from the method of sampling and the age distribution of the sample that it is not representative of the male population of Scotland at ages 17 to 42. The conclusions relevant to this inquiry are that maximum stature appeared to be reached by the 19th year and was 67 inches, and that stature decreased with increasing age.

Of their study the authors say "It may, therefore, be taken that the data abstracted from the records refer to a random sample within occupations and age groups, but that the numbers in the groups are not in proportion to their occurrence in civilian life". Since some occupations were better represented than others, and since differences in stature have frequently been shown to exist between occupations, the national average of 67 inches arrived at should be treated with some reserve. This estimate of Clements and Pickett does agree with Martin's for Scots aged 20 but Kemsley's analysis would suggest that maximum stature had not been attained before 22 years in the sample on which he reported.

In summary, the major surveys on record and available to us for scrutiny are as follows.

Beddoe made a nation-wide survey with the help of physicians, mostly rural. In making his estimates he does not appear to have allowed for the rural bias. His private returns, on which the estimates were based, totalled about 5500 for England, 1250 for Scotland and 100 for Ireland. He estimated 66.6 inches to be the maximum height for England and hazarded a guess for Scotland of 67.5 inches. On this basis, an estimate for the whole country might be 66.7 inches. The age of attainment of maximum height was assumed to be 23.

Roberts had measurements for a total of 28,228 men over 18 years of age of whom 24,225 were recruits, in part returns for the years 1862-3 when the qualifying height was 66 inches and in part for the recruits, already discussed by Beddoe, for the years 1864-5 when the qualifying height was 65 inches. The remainder, 4000 men, were either of the most-favoured class or artisans.

The British Association Anthropometric Committee added little to that total. They were of the opinion that there was no increase in height after age 25. Of Galton's sample of 6987 men we have no description.

On the basis of the evidence presented to it, the Royal Commission on Physical Deterioration was extremely critical of recruits as a sample of the community and decided it had no data with which to make secular comparisons of physique.

In this century Reid assembled measurements of nearly 800 Scottish university students and found that height increased after age 20. Tocher measured 2687 Scottish soldiers. His age of maximum height was between 22 and 23 years.

Cathcart measured 13,656 men, most of them urban. The estimated mean maximum height for the general population, 67.3 inches, is probably an underestimate for the years 1929-32. His ages at the maximum were between 21 and 25 years.

Martin had measurements of 90,000 men aged 20. This sample covered the whole country, the

first to do so since Beddoe's survey. The mean was 67.4 inches. It may be an underestimate if age 20 is below the age of attainment of maximum height.

Clements and Pickett's sample of 3692 Scotsmen gave a maximum of 67 inches at 19 years in 1941. Kemsley's sample of 26,703 in 1943 was of the civilian war-time population, almost entirely industrial, and regions were not correctly represented. His maximum of 67.2 or 67.3 inches at age 22 would almost certainly underestimate the height of the normal population.

The sequence of roughly comparable estimates of maximum height, in inches, with dates of measurement, is this: Beddoe (1870) 66.7, Cathcart (1929-32) 67.3, Martin (1939) 67.4 and Kemsley (1943) 67.2 or 67.3.

In view of the fact that Beddoe made no allowance for the excess of rural measurements and none for the sick and crippled not out and about to be measured, it may be taken that he overestimated mean maximum height. Since all the more recent analyses probably produced underestimates, the difference would appear to be in favour of the recent young adult population.

The sequence of estimates of age at which maximum height is attained suggests a gradual forward movement from age 30, or even later, to ages between 19 and 23.

INTERPRETATION OF THE RECORDS

Morant (1950) boldly attempted to co-ordinate the information from all the British published sources he could find, in order to discover what secular change, if any, had taken place in what he called the maximum mean height of the population. In addition he had some data for Army and Air Force personnel, during and subsequent to the 1939-45 war, which we have not been able to procure.

Maximum and Post-maximum Heights

All these Army and Air Force groups had maximum mean heights in excess of 67.7 inches, which they attained between 19 and just over 21 years of age. Morant's collected series totalled "more than two million men". Of these over 1,700,000 were army recruits between 1860 and 1913; 216,000 were conscripts medically examined in 1917-18 in the west midlands of England, and these were used to illustrate height "increasing to a maximum about age 25 and then declining with advancing age. This form is shown by all the longest series." (But there was no decline before age 50 in the British Association assembly of 1883 or in Tocher's Scottish soldiers before 37, the oldest measured, in 1915.) There were in addition the 90,000 males aged 20 measured in 1939 (Martin's

series). Two million of the total are thus accounted for. The nature of the residue is not completely specified numerically or in kind.

Of the army recruits enough has been said already to illustrate how difficult it is to define the population of which they are a sample in any particular year. Of the 1917-18 west midland series Morant says that in all age groups after 18 years many of the men had previously been examined for military service and rejected; and it is by no means certain that, even as recently as 1939, the militiamen at 20 years had attained their full stature. Morant describes two methods for estimating the age of attainment of maximum mean height within a group, and there is no doubt that the two earlier series of recruits would be satisfactory for comparing these, but there is no means of estimating with any precision what class or classes of the population are represented. The militiamen (1939) certainly give a clear picture of regional differences, indeed, the first adequate regional picture since Beddoe; but the question of attainment of maximum height goes unanswered. Between the earlier surveys and the most recent, a considerable amount of migration had taken place, migration which latterly, according to Martin, was selective as regards stature. There was also a great increase of urbanisation. Such changes must make the standardisation of surveys for regional differences, which Morant attempted, very largely a speculative process.

Effect of Selective Mortality over a Century

We have shown that the historical sequence of estimates of age at maximum height suggests a forward movement from age 30 or over to ages between 19 and 23. Morant takes a shift as established and bases his conclusions on the assumptions that age at maximum height was 26 a century ago and is $21\frac{1}{2}$ now. But the data are no more adequate to fix either point or to measure the change for the general population than they are to estimate mean height itself.

Morant further concludes that the secular change in time to attain maximum height has been greater in the lower classes of the population. Even in that respect, the picture is not uncomplicated. Here we may consider the complications in more detail. Two distinct concepts exist, as described in the introduction to this review, and they do not everywhere appear to have been clearly separated. The one is of the mean maximum stature of a population, the other of the maximum stature of an individual. In the population as a whole, high mean stature and high mean expectation of life are characteristic of the higher social classes. This fact could provide an explanation, as indeed was suggested by the British

Association (see p. 258), for the constancy of height with increasing age in the British Association 1883 series and possibly in Tocher's 1924 records as due to the earlier death, on the average, of the shorter individuals, so that the older groups of the population are progressively more selected by stature, and this might outweigh any shrinkage that might occur in the surviving individuals. Not only so, but if, at any period in history, this weeding-out began to operate in early adult years it would have the effect of raising the mean maximum stature after individual increase in height had ceased, though of course it could not affect the maximum stature of the individuals.

Effect of Initiation of Welfare Services

In later series of measurements, taken when social conditions had improved, a decline with age of the mean height is obvious, but the rate of decline is not uniform. In the records analysed by Kemsley (1950) for men measured in 1943 a decided dip occurs in the curve (Figure 1) about age 40. The curve of the means for women is shown with that for the men to illustrate that the dip is not peculiar to men and is not in consequence likely to be entirely due to the removal by the 1914-18 war of the fitter and taller who by 1943 would be in the older age groups. Clements and Pickett's (1952) data for men measured in 1941 in Scotland by local medical boards of the Ministry of Labour and National Service give evidence of a similar change in rate of decline. Regression coefficients of stature on age are shown for separate social classes as defined by the Registrar General (New classification; General Register Office, 1951) for age groups 17-19, 20-29 and 30-39, with a regression coefficient for the whole of - 0.032 inch per year. It is important to note that, in all but Class 1 and 2 combined, the regression is steeper for the 30-39 than for the 20-29 group. The steeper slopes in the later period are in keeping with a fall in height between those aged 31 and those aged 40 years. In the industrial workers, and others, measured by Cathcart, Hughes and Chalmers (1935) between 1929 and 1932 the steepening of the fall in height occurs about age 27. In Figure 2 the mean heights of employed men are shown for different age groups, only those groups with more than 200 men being used. A similar change in slope of the curve appeared among the unemployed and students, but the numbers in these groups were smaller so that the means were somewhat less reliable. All of these records (which were made independently at three different dates), show a "sudden" fall, or, to look at it the other way round, a "sudden" rise in mean height, in age groups born between 1900 and 1910. Although some of the effect may be

attributed to selective removal of the tall in the 1914-1918 war, the similar behaviour of the curve for women (Fig. 1) indicates that this was not the only cause.

A possible contributory cause may be found in the wealth of legislation affecting the welfare of mother and child which was enacted and brought into force in the years following the turn of the century. For a brief account see MacNalty (1950)

the heights and weights of London schoolchildren says "that children of today are not merely heavier or merely taller than their parents were, but are members of a generation altogether of greater physique". The social gradient would explain the absence of decline of height with age in Social Classes 1 and 2 of the 1941 Scotsmen, since these classes had little need, if any, of benefits from public health legislation.

and for greater detail Frazer (1950). The new developments included the establishment of welfare centres, the feeding of underfed children and the school medical service; improvements of sanitation and housing; and unemployment insurance. They did result in reduction of deformity and crippling and in progressively better growth among children, and there is still no evidence to show that better growth is not associated with higher maximum stature for the individual. Sir Allen Daley (1950) in his Report on

It is not a far step in reasoning to the suggestion that, of the populations sampled for the curves, the older parts (that is, those below the "dip") came from age groups which did not as young adults reach the mean maximum stature attained by the younger groups.

Morant's interpretation of the data differs from ours in the following respects. He claims that with advance in age a decline in height occurs in and may be "supposed the same" for all British series. But Quetelet, Beddoe and Roberts, and

the British Association Anthropometric Committee also, found no decline before age 50 and Tocher too found none before 37, the oldest group he examined. We have shown that all the subsequent series mentioned above show a decline and a change in rate of decline which coincides, regardless of the date of the survey, with birth in the first decennium of this century.

Morant next explicitly takes the curve relating the mean observed height to the age of the population as if it were the curve of an individual. "The decline following the attainment of skeletal maturity can be attributed to a normal shrinkage of the length of the body with advancing age". He is not entitled to do so on physiological or historical grounds. He sets up, only to knock

EVIDENCE OF SECULAR CHANGE FROM SCANDINAVIA

Support is given to our interpretation by two sets of Scandinavian records.

Swedish Hospital Outpatients

Holmgren (1952) reports measurements of over 46,000 outpatients at a Swedish hospital, taken between 1914 and 1930. The curve of stature against age for each of the years showed that in any one year stature decreased in the older groups, and that for all age groups (the data were grouped at 5-year intervals) stature was greater in 1930 than in 1914. The data for men are shown in

down, a hypothesis that the decline might be due to selective death rate, "taller men being supposed more prone to die at younger ages", which hypothesis, whether it was ever set up before or not, is certainly not supported by studies of social class or occupational mortality.

He sums up his interpretation in these words: "As the prime is reached to-day at a younger age than formerly the decline in adult life also starts earlier, and this implies that for ages after the early twenties people to-day are slightly less tall, on the average, than their recent ancestors were." We suggest that the change which has taken place in selective mortality and expectation of life with the development of welfare services has increased the proportion of the poorer social classes present in older age groups and so has reduced the mean heights of these groups. It is possible that the mean height of young adult groups has been reduced in the same way.

Figure 3 which compares the 1914 and 1930 series and Figure 4 which shows the unmistakable upward trend in the 26 to 30 year old group. By a series of comparisons at 10-year intervals of the heights of people born within some given interval, Holmgren deduced that individual stature was in fact increasing by 3 cm. between the ages of 26 and 70 years. Alternatively and, we believe, more reasonably, the survivors of every group would be more highly selected for height at each successive interval, because of the tendency for the taller to have a greater expectation of life. This is the effect of selective mortality, not on groups born at different times, but on a group born within one time interval, whose survivors are sampled at successive intervals. The picture is not analogous to that given by an instantaneous sample of all ages.

FIGURE 5. HEIGHT OF DANISH MALES AT AGES 18 TO 25, FOR DIFFERENT YEARS OF BIRTH FROM 1893 TO 1927.

*The Height scale is marked in units of 1 cm. with an arbitrary base line at 172 cm.

Danish Service Men

The final set of figures is for Danish service men, and was procured by courtesy of Dr. Hans F. Helweg-Larsen, Director of the Institute of Human Genetics in Copenhagen. They represent the results of medical examination of men for the Danish forces from 1911 to 1952. Military service is universal. All those called up are measured whether they are found fit for service or not, and all measurements are included. The total measured annually is between 33,000 and 40,000. The data are presented in Figure 5 and are self-explanatory. There is a tendency for the 18- and 19-year-old to be taller than the 20-year-old. Dr. Helweg-Larsen suggests that the younger groups contain many volunteers who present themselves before they are required to do so and are somewhat taller than the average of their age groups. The main body of men (20-year-old) numbers over 20,000 in each year and any of them who do not meet the requirements, *e.g.*, of stature, will be measured again in three subsequent years, after which, if they are still "substandard", they are no longer called to appear. Thus there is some duplication of measurement, but the 20-year-old represents a very good cross-section of the population, apart from those in university training, mostly of the higher social classes, who are deferred for up to five years. This deferred group makes its appearance from 23 to 25 years of age, and accounts for the rise in the second half of each curve in the figure. At each curve, a line is drawn representing 172 cm. (67.7 inches) and the figure clearly shows how the height of the young adult has increased over the years. In the early groups even the older and upper class student groups barely reached 172 cm. at an age when they must have been fully grown. All groups improve steadily until in the later ones all are above 173 cm. (68.1 inches). This gives clear evidence of improving stature in a population similar to our own.

SUMMARY AND CONCLUSIONS

To summarise briefly, it seems clear that in Britain our information is inadequate to show directly by comparing different series of records whether the mean maximum stature of the population has increased over the last 100 years or not.

Changing mortality rates and migration, with inadequate definition of the populations sampled, combine to obscure the picture. Of the recent data Martin's, which are the best in respect of geographical distribution, are not adequate to define either the mean maximum height of the male population, or the mean age at which it is attained. Of what happens in the individual after the maximum has been reached we know little or nothing. For women we have, at the moment, next to no information. Some may be forthcoming from Services records but there will be little of a representative kind with which to compare it.

It appears that the age at which mean maximum height is attained has moved forward but neither the details of the age-shift nor the heights attained can be assessed with any accuracy. On the assumption that a decline sets in as soon as maximum height has been attained in the individual, Morant argues that, because the mean maximum height of the population has apparently not changed, but is attained earlier, the population of above 23 years of age is not now at any age as tall as it was in the last century. The initial assumption is not supported by evidence and the more recently recorded decline of height with age is explicable on the altogether different grounds that the short now live longer. The view that mean maximum height may have risen with improved social conditions is supported by data from Sweden and Denmark whose populations resemble our own in social history.

The oft-repeated plea for an anthropometric survey of the nation has gone unattended now for nearly a hundred years. Not only one survey but a routine of surveys is still needed if we wish to know what changes are taking place in the physique of the nation. These should supplement and extend in both directions the measurements of schoolchildren; they should include repeated studies of representative samples into old age to establish the unknown pattern of change in physique of the ageing adult.

Our acknowledgements are due to *Acta medica scandinavica* for permission to reproduce Figures 3 and 4 from Professor Holmgren's paper, to Mrs. Laura Alstrup for referring our inquiry about Danish recruits to Dr. Helweg-Larsen, and to Dr. Helweg-Larsen for the transcripts of records.

SCANDRETT, F. J. **A modified all-glass apparatus for the determination of nitrogen by the micro-Kjeldahl method.** *Analyst*, 1953, **78**, 734-737. [Dept. Clin. Chem., Univ. Edinburgh.]

1430

DELAUNOIS, A. L. **A modified manometric Van Slyke apparatus.** *Arch. internat. Pharmacodyn.*, 1953, **94**, 426-429. [J. F. Heymans Inst. Pharmacol., Univ. Ghent.] French summary.

The taps in the Van Slyke apparatus are replaced by new vacuum-tight taps of special construction, based on the principle that if a leak should occur in the ground part of the stopcock the atmospheric pressure would push in a semi-liquid grease from a cup and seal the leak. The glass "cross connection" between the estimation chamber, the manometer and the stopcocks is replaced by a stainless steel tube connected at either end with the glass parts by heavy rubber vacuum tubing.—W. Godden.

MIETTINEN, J. K. and MOISIO, T. **A self-recording strip photometer for paper electrophoresis and paper chromatography.** *Acta chem. scand.*, 1953, **7**, 1225-1238. [Biochem. Inst., Helsinki.]

The construction and use of the instrument are described; a filter photometer is combined with a self-recording galvanometer from a polarograph. H. G. Bray.

1433

KEPES, A. **Séparation de mélanges biologiques à l'aide d'un nouvel appareil de répartition à contre-courant. [Separation of biological mixtures by a new counter-current distribution apparatus.]** *Bull. Soc. Chim. biol.*, 1953, **35**, 1243-1253. [Inst. Pasteur, Paris.]

Vol. 24, No. 2

The construction and working of a new apparatus is described. It has the following advantages; the number of elements can be varied at will; it functions continuously without shaking but by injection of the mobile phase by compressed air; it works equally well with the light or the heavy solvent as the mobile phase; it is rapid and automatic in its action and can work in air or in an inert gas. Its use in the separation of amino-acids is indicated, and it is shown to require less time and less solvent and to be more exact than chromatographic methods.—W. Godden.

1434

SHIPE, W. F., DAHLBERG, A. C. and HERRINGTON, B. L. **A semi-automatic cryoscope for determining the freezing point of milk.** *J. Dairy Sci.*, 1953, **36**, 916-923. [Dept. Dairy Indust., Cornell Univ., Ithaca, N.Y.]

1435

PERSIDSKY, M. D. **A vibratory microtome for sectioning living tissue.** *J. Lab. Clin. Med.*, 1953, **42**, 468-471. [Dept. Botany, Univ. Wisconsin, Madison.]

The microtome, which is described and illustrated, has been evolved from other models. The knife vibrates at a frequency of 100 to 300 cuts per sec. with an amplitude of 0.8 to 0.1 mm. The instrument is capable of cutting sections as thin as 3 μ . and of a smoothness and general quality approaching those obtained from embedded or frozen material.—W. Godden.

HERBAIN, M. Sur l'adaptation microanalytique de la réaction de Nessler. Application aux milieux biologiques. [Micro-analytical adaptation of the Nessler reaction. Application to biological media.] 1. Le dosage de 25 à 100 γ d'azote. [1. Estimation of 25 to 100 μ g. nitrogen.] 2. Le dosage de 5 à 10 γ d'azote. [2. Estimation of 5 to 10 μ g. nitrogen.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1031-1039; 1233-1241. [Serv. Sci. Roussel-Uclaf.]

1. Full details of apparatus, reagents and procedure are given.

2. The method described above for 25 μ g. N has been modified for the smaller quantities. An apparatus for destruction of organic matter by digestion with H_2SO_4 and subsequent distillation of NH_3 and its collection in acetic acid is illustrated and described. Over the range of 5 to 10 μ g. the results have an accuracy of ± 5 per cent.

W. Godden.

1453

VARNER, J. E., BULEN, W. A., VANECKO, S. and BURRELL, R. C. Determination of ammonium, amide, nitrite, and nitrate nitrogen in plant extracts. *Anal. Chem.*, 1953, **25**, 1528-1529. [Dept. Agric. Biochem., Ohio State Univ., Columbus 10.]

The procedure described permits the estimation of ammonium, amide, nitrite and nitrate N in a single sample of extract. Ammonium N is distilled from the sample buffered to pH 10; the residue is then treated with strong alkali and amide N is distilled off in steam. Treatment of the residue from this operation with 20 per cent. $FeSO_4$ reduces nitrite N to ammonia, which is then removed, and finally the addition of a saturated solution of Ag_2SO_4 catalyses the reduction, by the $FeSO_4$ present, of nitrate N to ammonia, which is removed and estimated.—H. G. Bray.

1454

KALMIKOV, P. E. Opređenje belka v pishche. [The estimation of protein in food.] *Gigiena Sanit.*, 1953, No. 4, 34-40. [Voen.-Med. Akad. Im. S.M. Kirov.]

From 3 to 5 g. food is ground up, moistened with 5 ml. concentrated H_2SO_4 (sp. gr. 1.84) and ground again until smooth. One ml. H_2O_2 is added and the mixture is heated with stirring for 20 to 30 min. on a water-bath, after which it is quantitatively transferred to a 250-ml. flask and made up to standard volume. The final liquid should be homogeneous. One ml. of homogenate is heated with 1 ml. concentrated H_2SO_4 and 3 to 4 drops of H_2O_2 till a colourless solution is obtained. The solution is diluted to 35 to 40 ml. with distilled water and almost neutralised with NaOH (the amount being ascertained beforehand). The pH is adjusted to 5.5 to 6, after which the solution is made up to standard volume. The ammonia N is estimated colorimetrically with Nessler's reagent, the colour being compared with standard colours. Results obtained by this method and the normal Kjeldahl method indicate that the error of the colorimetric method is greater than that by the Kjeldahl method, being about 7 per cent., but this is within the limits of error of visual colorimetry. The application of photocolorimeters will probably cut this error down to 1 to 2 per cent. The main advantage of the method is that it is time-saving.

W. Hughes.

1455

WALDMAN, R. K., KRAUSE, L. A. and BORMAN, E. K. Determination of total protein in small quantities of spinal fluids: confirmation of the accuracy of a colorimetric method using Folin-Ciocalteu reagent in the presence of copper. *J. Lab. Clin. Med.*, 1953, **42**, 489-492. [Bur. Labs., Connecticut State Dept. Health, Hartford.]

The method of Daughaday *et al.* (Abst. 36, Vol. 23) is applicable to 0.2 ml. serum or plasma and is relatively little affected by the albumin:globulin ratio and so is preferable to turbidimetric methods.

H. G. Bray.

1456

KOZLOVSKY, V. S. Prostoi metod opredeleniya kolichestva obshchego belka i belkovykh fraktsii v syvorotke krovi. [Simple method of estimating total protein and protein fractions in blood serum.] *Sovet. Med.*, 1953, **17**, No. 3, 42-43. [Klin. Lab., Donets. Inst. Fiziol. Trud.]

Total protein is estimated by Shul'tsev's method (*Sovet. Med.*, 1947, No. 3; 1949, No. 6). This is based on the appearance of a white ring at the boundary between a layer of HNO_3 and the diluted blood serum when the latter is carefully poured on

to the HNO_3 . Under these conditions, if the ring appears in between 2 and 3 min. the protein content is 0.03 per cent. The applications of this method to the estimation of fibrinogen in plasma, and of albumins is described; the dilution of the serum is adjusted so as to give a white ring within a specified time.—W. Hughes.

FREIMUTH, U. Studien über die Eiweisskörper des Milchserums. 1. Fraktionierung durch Aussalzen und Elektrophorese. [The proteins of whey. 1. Fractionation by salting-out and electrophoresis.] *Biochem. Ztschr.*, 1953, **324**, 476–484. [Inst. Tierzuchtforsch., Deutsch. Akad. Landwirtschaft., Berlin.]

The solubility curve of whey having indicated the presence of 2 protein bodies, these were salted out by Na sulphate and separated into an albumin and a globulin fraction. Electrophoresis of the whey and of the salted-out preparations permitted the differentiation of 2 protein bodies in the albumin fraction, and at least 3 in the globulin fraction with different migration rates. For precipitation of the proteins separated by salting out, the usual protein precipitants, tungstic acid, Almén's reagent, and 10 per cent. trichloroacetic acid, proved about equally effective. At boiling temperature 4 per cent. trichloroacetic acid was also satisfactory, but at room temperature about 50 per cent. of the N present remained in solution. By coagulation at boiling temperature of the solution weakly acidified with acetic acid, only 69 per cent. of the N present was precipitated.

phoretic estimation of protein fractions on paper.] *Dokl. Akad. Nauk S.S.S.R.*, 1952, **87**, 1035-1038. [Nauch.-Issled. Inst. Pereliv. Krov., Leningrad.]

Strips of filter paper 3×35 cm. were fixed in a hermetically sealed glass tank, the bottom of which was covered with distilled water to give 100 per cent. humidity. The ends of the strips were immersed in 2 vessels at different heights in the tank. These vessels were fitted with needle electrodes separated from the buffer solutions contained in them by glass labyrinths. The filter paper passed over 2 glass rods and it was at these points that the drops of protein solution were placed. The papers to be used for electrophoresis were left for 24 hr. in the tank before test. Non-dialysed serum or plasma, 0.02 to 0.04 ml., was placed on the paper and treated for 6 to 8 hr. at 260 to 270 volts and 1.5 to 2.0 milliamps. The spots after development with a dye were not extracted as is normally done; instead, the amount of light passing through the spots was measured directly *in situ* by means of a specially constructed spectrophotometer. The whole apparatus and technique is claimed to be much simpler than electrophoretic apparatus now in use. W. Hughes.

1467

NIKKILA, E., HAAHTI, E. and PESOLA, R. On the technique of preparative electrophoresis of proteins in supporting medium (starch). *Acta chem. scand.*, 1953, **7**, 1222-1223. [Dept. Med. Chem., Univ. Helsinki.]

The preparation of the column is described. It was found advisable to make the run with the column held vertically. Bilirubin can be used for detection of the protein fractions, but if coloured fractions are not desired, ultraviolet fluorescence may be employed. At the end of the run the location of the bands can be estimated by pressing a filter paper strip against the side of the wet column and then staining it with bromophenol blue. Elution with an alkaline buffer containing glycine is recommended.—H. G. Bray.

"Overlapping" amino-acids are those which do not form discrete bands on circular paper chromatograms developed by mixtures of *n*-butanol, acetic acid and water (40 : 10 : 50). These mixed bands are cut out and used as the "wick" by means of which a second chromatogram is irrigated, using as solvents pyridine and water (80 : 20), pyridine, amyl acetate and water (10 : 10 : 7), and pyridine, iso-amyl alcohol and water (10 : 5 : 5). By this technique the following groups can be separated and estimated : leucine, isoleucine, valine, methionine ; γ -aminobutyric acid, tryptophan ; α -amino butyric acid, tyrosine ; β -alanine, proline ; glutamic acid, threonine ; glycine, serine, aspartic acid ; arginine, asparagine ; lysine, histidine. Results are given for the analysis of hydrolysates of casein and edestin.—H. G. Bray.

MEISEL', M. N. and TROFIMOVA, N. P. Novyi mikrobiologicheskii metod opredeleniya triptofana. [A new microbiological method of estimating tryptophan.] *Mikrobiologiya*, 1953, **22**, 385-390. [Inst. Mikrobiol., Acad. Nauk SSSR, Moscow.]

Saccharomyces cerevisiae was chosen as the indicator organism, since in addition to biotin and pantothenic acid the strain used, T1, requires the presence of tryptophan for development. Preliminary tests in which a Rider medium was used as the base showed that none of the water-soluble vitamins tested could replace tryptophan. In conjunction with the Rider medium a yeast hydrolysate was used, in which the tryptophan was destroyed by ultraviolet radiation, all the other vitamins and amino-acids required for growth of the organism being left unaltered. It was shown that none of the other amino-acids composing the yeast hydrolysate could replace tryptophan or favour its biosynthesis. Purine and pyrimidine bases were similarly inactive. Compounds related to tryptophan were tested for biological activity, and of these only indole was found to be capable of replacing tryptophan. Indole was, however, easily removed by extraction of the aqueous extract with ethyl ether. The nutrient medium was therefore made up to contain the following percentages: sucrose 2, $(\text{NH}_4)_2\text{SO}_4$ 0.3, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 0.07, NaCl 0.05, $\text{Ca}(\text{NO}_3)_2$ 0.04, KH_2PO_4 0.1, K_2HPO_4 0.01, irradiated yeast autolysate 0.5. The sensitivity of the method is 0.5 $\mu\text{g.}$ per ml. The advantage of the method is that there is no need to use a complex nutrient medium containing pure vitamins and amino-acids.—W. Hughes.

1478

DOBYNS, B. M. and BARRY, S. R. The isolation of iodinated amino acids from thyroid tissue by means of starch column chromatography. *J. Biol. Chem.*, 1953, **204**, 517-531. [Dept. Surg., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

The starch column chromatography technique of Moore and Stein (Absts. 3939, Vol. 18; 1704, Vol. 19) was employed for the separation. Radioactive thyroid tissue was obtained from rats which had received injections of ^{131}I shortly before death. An alkaline solvent of *n*-butanol, propanol and 0.05 *N* Na_2CO_3 (1 : 2 : 1) was found preferable to an acid solvent and the addition of $\text{Na}_2\text{S}_2\text{O}_3$ just before hydrolysis and to the hydrolysed sample just before it was run on to the starch column overcame undesirable reactions such as interchange of I between compounds, freeing of I from amino-acids and synthesis of compounds *in vitro*. Thyroxine, diiodotyrosine, monoiodotyrosine, inorganic iodide and 2 unknown iodinated compounds were separated. There was progressive accumulation of ^{131}I in the thyroxine fraction from the thyroid in groups of animals killed 4, 24 and 48 hr. after the administration of ^{131}I . One of the unknown compounds, at first thought possibly to be identical with an unknown compound

recently identified by Gross and Pitt-Rivers (*Lancet*, 1952, **262**, 439) as triiodothyronine, has been proved by work performed since the above paper was prepared not to be this compound.

W. Godden.

1479

BLASS, J., MACHBOEUF, M. and REBEYROTTE, P. Application de l'électrorhéophorèse à l'identification de divers amines biologiques dans les mélanges d'acides aminés. [Application of electrophoresis to the identification of biological amines in mixtures of amino-acids.] *Bull. Soc. Chim. biol.*, 1953, **35**, 953-957. [Serv. Chim. Biol., Inst. Pasteur, Paris.]

By means of the procedure described ethanolamine and glucosamine can be identified when mixed with amino-acids. It is suggested that electrophoresis may be used for "second-dimensional" separation of amino-acids which are not sufficiently separated by one-dimensional paper chromatography.—H. G. Bray.

1480

MELLON, E. F., KORN, A. H., VIOLA, S. J., MILLER, N. and HOOVER, S. R. Isolation of amino acids by distillation of the acetylated amino acid ethyl esters. *J. Amer. Chem. Soc.*, 1953, **75**, 5524-5528. [E. Reg. Res. Lab., Philadelphia, Pa.]

Amino-acids in protein hydrolysates were acetylated and their ethyl esters were prepared and separated by methods which are outlined. Difficulties were encountered in the preparations, but enough material was obtained to show that separation of fractions rich in alanine, valine, leucine, isoleucine, proline, aspartic acid, glutamic acid, methionine and phenylalanine was possible. From selected fractions alanine, valine, leucine and isoleucine were obtained in pure form.—D. Harvey.

1481

FOLKES, B. F. The *p*-hydroxydiphenyl test for acetaldehyde: the determination of alanine and threonine in protein hydrolysates. *Analyst*, 1953, **78**, 496-498. [Dept. Botany, Univ. Bristol.]

A modified procedure for the estimation of acetaldehyde is described. Alanine is estimated by a modification of the procedure of Virtanen and Rautanen (Abst. 37, Vol. 17): the protein hydrolysate is treated with ninhydrin and acetaldehyde is aspirated into sodium bisulphite for estimation. Interference by other amino-acids is considered. Threonine is estimated by a modification of the method of Winnick (*J. Biol. Chem.*, 1942, **142**, 461): the protein hydrolysate is treated with periodic acid in a Conway unit, the acetaldehyde formed diffuses into bisulphite and is then estimated by the method described.—H. G. Bray.

ISHERWOOD, F. A. and HANES, C. S. **Separation and estimation of organic acids on paper chromatograms.** *Biochem. J.*, 1953, **55**, 824-830. [Low Temperature Res. Stat., Univ. Cambridge.]

Single-phase *n*-propanol-ammonia mixtures are used as developing solvents, the concentrations depending on the acids studied, e.g., 70:30 (v/v) for lower fatty acids, propanol: ammonia: water 60:20:20 for dicarboxylic acids. Spraying reagents used are thymol blue and ammoniacal AgNO₃. A method is described for the estimation of ammonium salts of organic acids separated by paper chromatography. The areas of paper containing the salts are cut out and extracted with 35 per cent. ethanol in a stream of CO₂-free air under carefully controlled conditions. A thymol blue glycine reagent is added and the colour intensity measured. The colour of the indicator is inversely proportional to the concentration of the salt from about 80 to 20 per cent. neutralisation. The relation between the quantity $\log [(1/R_F) - 1]$ and the number of carbon atoms in the acids is discussed. An apparatus is described for purification of paper before use.—H. G. Bray.

1490

DUNCAN, R. E. B. and PORTEOUS, J. W. **The identification and determination of the lower straight-chain fatty acids by paper partition chromatography.** *Analyst*, 1953, **78**, 641-646. [Dept. Biol. Chem., Univ. Aberdeen.]

The developing solvent used for ascending paper chromatography is the organic phase of *n*-butanol saturated with 1.5 N ammonia. The indicator spray is a mixture of methyl red and bromothymol blue in an ethanolic formalin solution. The conditions for obtaining reproducible chromatograms from mixtures in which the amount of each acid ranges from 5 to 80 μ g. are considered.

H. G. Bray.

NIJKAMP, H. J. **A simple chromatographic method for the determination of the C₁₀-C₂₀ saturated straight-chain fatty acids.** *Nature*, 1953, **172**, 1102-1103. [Lab. Animal Physiol., Agric. Univ. Coll., Wageningen, The Netherlands.]

The acids are separated quantitatively on a 9-cm. column of silica gel. The column is tinted with bromothymol blue, neutralised with methanolic ammonia solution and saturated with methanol and the chromatogram is developed with *iso*-octane saturated with 95 per cent. methanol.

Mixtures containing about 0.5 mg. of the different acids gave recoveries of 95 to 105 per cent. of each acid.—G. A. Garton.

1492

EMMERIE, A. **On the paper chromatography of α -glyceryl ethers.** *Rec. Trav. chim. Pays-Bas*, 1953, **72**, 893-896. [Lab. Hyg., Univ. Utrecht.]

α -Glyceryl esters of cod liver oil are oxidised with periodic acid and the resulting aldehydes are extracted with benzene and separated by chromatography on filter paper impregnated with paraffin or cetyl acetate. The mobile phase is aqueous methanol or ethanol and the detecting agent a mixture of fuchsin and sulphurous acid which produces red-violet spots. An ascending technique is used.—H. G. Bray.

1493

KERR, L. M. H. and BAULD, W. S. **The chromatographic separation of free and combined plasma cholesterol.** *Biochem. J.*, 1953, **55**, 872-875. [Dept. Biochem., Univ. Edinburgh.]

Cholesterol may be separated from its esters on an alumina column with light petroleum and then benzene as mobile phase. Cholesteryl esters may be estimated directly by means of the Liebermann Burchard reaction. A method is described for the estimation of free and combined cholesterol in plasma.—H. G. Bray.

1494

HUTT, H. H., WEATHERALL, H. and CULSHAW, T. **The determination of total phosphatide in commercial lecithin.** *Analyst*, 1953, **78**, 712-716. [J. Bibby and Sons, Ltd., King Edward St., Liverpool 3.]

An improvement of an earlier method (Title 32, Vol. 14) for estimating acetone-insoluble matter is described. The difference between matter insoluble in acetone estimated by this method and matter insoluble in light petroleum is suggested as giving a suitable measure of phosphatide content.

W. Godden.

1495

HADORN, H. and JUNGKUNZ, R. **Über eine gravimetrische Cholinbestimmungsmethode sowie über den Gehalt an Lecithin, Sphingomyelin und Kephalin in Hühnereiern und Eipulvern.** [Gravimetric estimation of choline and the lecithin, sphingomyelin and cephalin content of hen eggs and egg powders.] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 333-347. [Lab. VSK, Basle.] French and English summaries.

Total lipid is extracted by means of a mixture of ethanol and benzene and weighed. The extracted material is hydrolysed with HCl in an autoclave and choline is precipitated as its reineckate and

N.A. and R., April 1954

weighed. Lipid phosphoric acid and N can be estimated by application of saponification and Kjeldahl procedures, respectively, to the total lipid fraction. From these data the lecithin, cephalin and sphingomyelin content of egg powders can be calculated. Whole egg powders contained 1.60 to 1.92 per cent. of choline.

H. G. Bray.

FONNESU, A. Photometrische Anpassung für die Mikrobestimmung der Essigsäure im Harn. [Photometric adaptation for the micro-estimation of acetic acid in urine.] *Biochem. Ztschr.*, 1953, **324**, 512-516. [Inst. Allg. Pathol., Univ. Perugia.]

The urine is cleared and freed from reducing material, and evaporated, and the residue is esterified with methanol. The methyl acetate formed is distilled over free from most other esters. It is then saponified and impurities such as formic acid and H₂S are oxidised by K₂Cr₂O₇ in 50 per cent. H₂SO₄, and finally acetic acid is oxidised by adding AgNO₃ and increasing the H₂SO₄ concentration to 60 per cent. The amount of acetic acid present is calculated in terms of the difference

in the spectrophotometric extinction value caused by the last stage in the process. The method is applicable to from 0.1 to 1.0 mg. acetic acid and in 10 control experiments the average recovery was 96 per cent., the range being from 85 to 107 per cent.—H. G. Bray.

1500

HARPER, W. J. Direct chromatographic determination of acetic, propionic and butyric acids in cheese. *J. Dairy Sci.*, 1953, **36**, 808-816. [Dept. Dairy Technol., Ohio State Univ., Columbus.]

The method consists in chromatography on a specially prepared silicic acid column; the acids are eluted with mixtures of chloroform and butanol, the concentration of the latter being increased as development continues. Acids containing more than 5 carbon atoms are removed first and acetic acid last. Results obtained with this procedure were in good agreement with those given by a similar procedure in which the acids were separated from cheese by distillation before chromatography. In control experiments recoveries of added acids of more than 90 per cent. were obtained.—H. G. Bray.

1501

McROBERTS, L. H. Report on acetic and propionic acid mold inhibitors in bread. *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 769-781. [Food and Drug Admin., Dept. Health, San Francisco, Calif.]

The method previously adopted (*ibid.*, 1951, **34**, 284) has been submitted to collaborative trials on milk bread and whole wheat bread with added propionate and Na diacetate. The results show that the method is adequate for general use in bread analysis. Lactic acid in amounts of 0.4 to 1.8 per cent. does not interfere in the estimation of acetic, propionic or butyric acid. There was no definite proof of the presence of butyric acid in the authentic milk bread.—W. Godden.

1502

VAN DUUREN, A. J. The determination of organic acids in plant material by means of paper chromatography. *Rec. Trav. chim. Pays-Bas*, 1953, **72**, 889-892. [Inst. Rationele Suikerprod., Bergen op Zoom.]

The solvent mixture used for the separation of oxalic, citric, tartaric, malonic, malic, succinic and lactic acid was propanol : ethanol : buffer (1.6 N with respect to ammonia and ammonium carbonate) in the proportion 10 : 60 : 30. Detection was by spraying first with 4 per cent. formaldehyde in ethanol and then with a solution of KI 0.3 per cent., KIO₃ 0.2 per cent. and starch

0.2 per cent., blue spots against a white background being obtained. An ascending technique was found to be preferable to a descending.

1507

GEY, K. F. **Zur quantitativen Bestimmung der Zitronensäure in Blut und Urin mittelst Pentabromazetonbildung. [Quantitative estimation of citric acid in blood and urine by conversion to pentabromoacetone.]** *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 21-41. [Hoffmann La Roche and Co., AG., Basle.] French and English summaries.

After a critical examination of different methods a technique was evolved for routine estimation of citric acid in concentrations of 25 to 200 μ g., with an error of ± 4 per cent. Recoveries of citric acid added to blood and urine were from 95 to 102 per cent. The most suitable protein precipitant was found to be 10 per cent. trichloroacetic acid.

Inorganic Constituents

1514

WICHMANN, H. J. **Ash determinations in foods with an alkaline balance. 6. Reaction of sodium carbonate with calcium phosphates in the ashing of milk.** *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 979-992. [Food and Drug Admin., Dept. Health, Washington, D.C.]

Earlier work with mixtures of pure Ca phosphates and alkali carbonates (Absts. 1834, Vol. 12 ; 2816, Vol. 13) has been extended to a study of the ash from slightly soured milk before and after neutralisation and with and without the addition of sodium lactate. The water-insoluble ash of unneutralised milk contained mixed NaCa and KCa phosphate with very little CO_2 . This introduction of both Na and Ca into the insoluble ash of milk confirms the findings of Hillig (Abst. 2783, Vol. 11). The neutralisation of milk with Na_2CO_3 or the addition of Na lactate introduces CO_2 into the insoluble ash as basic alkali-Ca phosphates or carbonated hydroxyapatite. The results obtained depend on the degree of neutralisation and the temperature of ashing.—W. Godden.

1515

BREYER, B. and McPHILLIPS, J. **The indirect polarographic determination of calcium by chloranilic acid.** *Analyst*, 1953, **78**, 666-669. [Physicochem. Labs., Fac. Agric., Univ. Sydney.]

Calcium is precipitated by chloranilic acid and, without removal of the precipitate, the excess reagent is estimated polarographically. The concentration of Ca which may be used ranges from $1.3 \times 10^{-4} M$ to $1.2 \times 10^{-2} M$ and the method is accurate to within ± 3 per cent. Co, Zn, Pb, Mn, Cd, Ni, Al, Cu and Ag ions interfere : Li, Ba, Mg, Cr, Sr, ferric and mercuric ions interfere only if present in concentrations greater than a critical value. The method is applicable to serum and to milk.—H. G. Bray.

KOMLEV, A. I. and TSIMBALISTA, L. I. *Primenenie osadochnoi khromatografii v kachestvennom polumikroanalize. [Application of precipitation chromatography in qualitative semimicro-analysis.] Zh. Anal. Khim.*, 1953, **8**, 217-219. [Lvov. Gosud. Univ. Im. I. Franko.]

Chlorides, iodides and bromides are separated chromatographically on a column 1 cm. long and containing about 0.1 to 0.2 g. Al_2O_3 mixed with 1 per cent. by weight of AgNO_3 or Ag_2SO_4 . Three drops of a solution as weak as 0.001 *N* of the respective ions are sufficient to give a chromatogram. The principle is precipitation of the halide by the silver salt, separation depending on the difference in the solubilities of the silver halides. The chromatograms are developed in sunlight; the first zone is yellow (AgI), the second blue-grey (AgBr) and the third violet-grey (AgCl). Limits of identification are 8 μg . for I, 14 to 15 μg . for Br and Cl, and the limiting concentrations are 1 : 7000 for I and 1 : 4000 for Cl and Br.

Ag, Hg and Pb are chromatographically separated on an Al_2O_3 column moistened with KI solution. Three zones, yellow (AgI), green (Hg_2O_2) and yellow (PbI_2), are obtained. Mixtures such as Bi-Cd, Cu-Cd and Sn-Sb are separated by using a saturated solution of Na_2S or $(\text{NH}_4)_2\text{S}$ as precipitant.—W. Hughes.

1524

SAMSON, S. *A new method for the quantitative determination of chloride in plant material. Nature*, 1953, **172**, 1042. [Agric. Exp. Stat., Groningen, Holland.]

An electrometric titration procedure is described. Two silver-silver chloride electrodes dip into an unfiltered extract of ground or dried plant material which is titrated with AgNO_3 . The end-point is indicated by an abrupt change in the direction of the galvanometer deflection.—H. G. Bray.

1525

HOSTE, J., EECKHOUT, J. and GILLIS, J. *Spectrophotometric determination of copper with cuproine. Anal. chim. Acta*, 1953, **9**, 263-274. [Lab. Anal. Chem., Univ. Ghent.] French and German summaries.

The spectrophotometric properties of the copper complex with 2 : 2'-diquinolyl (cuproine) were studied together with its partition coefficient between water and isoamyl alcohol, its stability with respect to colour and the influence of temperature, ions and excess reagent on its formation. Analytical procedures are described for the estimation of Cu in plants, animal tissues, blood and water, lampblack and steel.—H. G. Bray.

1526

FORSTER, W. A. *The determination of copper in plant material. Analyst*, 1953, **78**, 614-616. [Agric. Res. Counc. Unit Plant Nutrit., Long Ashton Res. Stat., Bristol.]

Details are given of a colorimetric method using diethyl-dithiocarbamate; ammonium ethylenediamine tetra-acetate is used to prevent interference by Co, Fe, Mn and Ni. Al, Zn, Ca, Mg and P do not interfere. CCl_4 is used to extract the coloured complex. The method gives results in good agreement with those obtained with a dithizone procedure.—H. G. Bray.

1527

HUBBARD, D. M. and SPETTEL, E. C. *Microdetermination of copper in biological material. Improved dithizone - polarographic method. Anal. Chem.*, 1953, **25**, 1245-1247. [Kettering Lab., Dept. Prev. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Urine samples, 100 ml. or less, and blood and tissue specimens, 10 g. or less, are wet-ashed and Cu is extracted with a solution of dithizone in CHCl_3 . The extract is washed with KI and HCl and the complex is decomposed by treatment with acid bromine water. The Cu is thus transferred to the aqueous phase, which is evaporated to dryness; the residue is dissolved in a citrate buffer and the solution is examined polarographically.—H. G. Bray.

1528

BEVERIDGE, J. S., HUNTER, G. J. and MACNULTY, B. J. *The determination of microgram quantities of fluoride. 2. The determination of fluoride in waters and sewage effluent using the aluminium - haematoxylin complex. Anal. chim. Acta*, 1953, **9**, 330-337. [Chem. Inspectorate, Minist. Supply, Kidbrooke, London.] French and German summaries.

It was shown that the method previously described by the authors (*Anal. chim. Acta*, 1953, **8**, 351) is applicable to the estimation of amounts of F down to 0.1 p.p.m. in sea, river and potable waters and in sewage effluent, without previous separation by distillation. For sea water a calibration curve using artificial sea water is advisable. Values are given for waters of some British rivers and for potable water from different districts.

H. G. Bray.

ICKEN, J. M. and BLANK, B. M. *Determination of fluorides. Spectrophotometric adaptation of method of Association of Official Agricultural Chemists. Anal. Chem.*, 1953, **25**, 1741-1742. [Food Res. Labs., Inc., Long Island City, N.Y.]

The fluoride is isolated by distillation and the neutralised distillate is treated with a thorium alizarin reagent, the absorbance of the mixture being measured spectrophotometrically at 525 m μ .
H. G. Bray.

1530

GOL'DBERG, G. S. K opredeleniyu ftora v zubakh. [Estimation of fluorine in teeth.] *Stomatologiya*, 1953, No. 2, 8-9. [Kaf. Obshch. Khim., Med. Stomatol. Inst., Leningrad.]

Three methods were used for the estimation of fluorine in teeth: (a) an ashing method for estimating inorganic F; (b) a method involving extraction with glycerol plus alkali to estimate organic F; (c) the Tananaev method which involves distillation of the F as fluosilicic acid into alcoholic potash. All three methods gave identical results, 0.38 per cent. No F was detected in the glycerol-alkali aqueous extract, which indicates that all the F is present in inorganic form. There is no need to ash the teeth prior to F estimation. Distillation using the Tananaev method is sufficient.

W. Hughes.

1531

CREMER, H. D. and VOELKER, W. Die Bestimmung von Fluor in Knochen und Zähnen. [Estimation of fluorine in bones and teeth.] *Biochem. Ztschr.*, 1953, **324**, 89-92. [Physiol. Chem. Inst., Univ. Mainz.]

The ashed material is distilled at 135° C. in the presence of perchloric acid and silica, the fluorine present distilling over in steam as H₂SiF₆. The distillate is concentrated to about 1 ml. and the F content is estimated in terms of the reduction in colour of an iron salicylate reagent. The method is applicable to the estimation of from 5 to 50 μ g. F, the error ranging from ± 4 to ± 2 per cent.—H. G. Bray.

1532

OLIVER, R. Use of a scintillation gamma counter for the estimation of iodine 131 in liquid samples. *Brit. J. Radiol.*, 1953, **26**, 663-664. [Dept. Radiotherapy, Churchill Hosp., Oxford.]

1533

VAN ZYL, A. A critical assessment of the distillation technique for the estimation of protein-bound iodine with suggested improvements. *S. African J. Med. Sci.*, 1953, **18**, 61-78. [Dept. Physiol., Univ. Witwatersrand, Johannesburg.]

After a critical consideration of different techniques and apparatus for the estimation of protein-bound iodine by distillation, the Barker method (Abst. 1630, Vol. 18) and the Connor apparatus (Abst. 1739, Vol. 19) were submitted to detailed tests. The technique was modified and the design of the apparatus was altered. A diagram

of the proposed still head is given. It is shown that chromic, chloride and sulphate ions may have effects on the final colorimetric reaction of arsenious acid and ceric sulphate which may be responsible in part for unsatisfactory I values. The new procedure is described in detail, and it is claimed that reproducible results can be obtained with 1-ml. samples of serum.—W. Godden.

1534

ELLIS, G. H. and DUNCAN, G. D. Distillation of micro quantities of iodine. Application to determination of protein-bound iodine in bovine blood serum. *Anal. Chem.*, 1953, **25**, 1558-1559. [U.S. Plant Lab., Bur. Plant Indust., U.S. Dept. Agric., Ithaca, N.Y.]

A suitable still is described, together with modifications of the method of Chaney (Abst. 52, Vol. 10). In control experiments recoveries of 96 per cent. were consistently obtainable.—H. G. Bray.

1535

WEYL, B. Methodischer Beitrag zur Serumeisenbestimmung nach Fuhrmann und Barkemeyer. (Vereinfachungen und Fehlerquellen.) [Fuhrmann and Barkemeyer's method of estimating iron in serum. Simplifications and sources of error.] *Ztschr. ges. inn. Med.*, 1953, **8**, 758-759. [Inn. Abt., Allg. Krankenhaus, Hamburg, Ochsenzoll.]

1536

PETERSON, R. E. Improved spectrophotometric procedure for determination of serum iron using 4, 7-diphenyl-1, 10-phenanthroline. *Anal. Chem.*, 1953, **25**, 1337-1339. [Dept. Biochem., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington 12, D.C.]

A procedure is described which is applicable to serum, 1 to 2 ml., and to wet-ash digests of biological material. Diluted serum is treated with a mixture of trichloroacetic acid and thioglycolic acid and to the supernatant liquid is added a solution of 4 : 7-diphenyl-1 : 10-phenanthroline in amyl alcohol. The alcohol layer is separated and the colour is estimated at a wavelength of 535 m μ .

H. G. Bray.

1537

IRVING, H. M. and BUTLER, E. J. A reversion method for the absorptiometric determination of traces of lead with dithizone. *Analyst*, 1953, **78**, 571-578 (with discussion 578-580). [Inorg. Chem. Lab., South Parks Rd., Oxford.]

1538

WÄHLIN, E. Polarographic determination of traces of metals in organic material. Determination

of Pb, Cu, Cd, Ni, Zn and Fe. *Acta chem. scand.*, 1953, **7**, 956-968. [Royal Inst. Technol., Stockholm.]

A wet-ashing method is described for cellulose, carboxymethyl cellulose and dry yeast. Two samples are used for polarography. In one Pb is estimated after precipitation with ammonia in the presence of ferric iron, the precipitate being separated and dissolved in acid. In the second Fe is estimated in perchloric acid solution and Cu, Cd, Ni and Zn after the addition of hydroxylamine sulphate and pyridine.—H. G. Bray.

1539

GEE, A. and DEITZ, V. R. **Determination of phosphate by differential spectrophotometry.** *Anal. Chem.*, 1953, **25**, 1320-1324. [Nat. Bur. Standards, Washington 25, D.C.]

The high precision, 1 in 3000, of the method described is due to the fact that it is based on a comparison of the unknown with an accurate standard. The colour reaction used is the formation of a molybdivanadophosphate complex.

H. G. Bray.

1540

SCHOBER, R. and FRICKER, A. Eine neue Methode zur Bestimmung des Kaliumgehaltes der Milch. 2. Der Kaliumgehalt Allgäuer Kuhmilch bei normaler und durch Mastitis gestörter Sekretion. [New method for estimating potassium in milk. 2. Potassium content of milk of Allgäu cows, normal and with mastitis.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **97**, 177-182. [Staatl. Milchwirtsch. Lehr-Forschungsanst., Wangen, Allgäu.]

The method is a modification, with Na tetraphenyl borate, of that described in the first paper of the series (Abst. 1308, Vol. 23). The K content of the milk of individual cows varied between 137.7 and 177.3 mg. per 100 ml. and of mixed milks between 136.0 and 179.4 mg. per 100 ml. Variation due to mastitis was slight.—H. G. Bray.

TERRIER, J. Le dosage du sel dans le pain. [Estimation of salt in bread.] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 403-405. [Lab. Cantonal, Geneva.] German and English summaries.

Enzyme Activity

1545

NARDI, G. L. **Radioactive measurement of proteolytic activity.** *Science*, 1953, **118**, 299-300. [Dept. Surg., Harvard Med. Sch., Boston, Mass.]

This is a method for estimation of proteolytic activity in body fluids. Albumin labelled with ^{131}I and free of unbound inorganic ^{131}I is digested for 20 min. with the proteolytic solution. The protein is then precipitated with 1 ml. β -naphthalenesulphonic acid and 1 ml. human serum albumin as carrier. The radio-activity of the supernatant solution is proportional to the proteolytic activity of the enzyme.—D. Duncan.

1546

BOWLBY, C., TUCKER, H., MILLER, B. S. and JOHNSON, J. A. **A comparison of methods for determining proteolytic activity.** *Cereal Chem.*, 1953, **30**, 480-491. [Dept. Flour and Feed Milling Indust., Kansas Agric. Exp. Stat.]

In evaluating the action of proteinase in dough 8 methods of estimation and 7 preparations were tested in 46 combinations. The preparations were a malted wheat flour, papain, trypsin, a bacterial enzyme, Protease-15, and 3 fungal preparations, Rhozyme P-11, Rhozyme-S and Protease-26. Regression coefficients between enzyme concentration and activity were calculated for each of the enzymes and methods. The variation in relative activity of the enzymes between methods was

N.A. and R., April 1954

evaluated by comparing the ratios of the quantities of enzymes required for equivalent activity when analysed by the several methods.

There was generally good agreement for results by the Farinograph dough consistency technique used as control and the Hb-Kjeldahl, Hb-Beckman spectrophotometric, bromosulphalein and formol titration methods for malted wheat flour, Rhozyme P-11, Rhozyme-S and Protease-26. The two techniques involving gluten digestion and the one involving clotting of milk did not give results similar to those by the other methods.

There was no single relationship between the results for a particular method and those by the Farinograph for all preparations. If, however, preparations were classified according to origin, animal including bacterial, and fungal and plant, the results for Hb digestion, bromosulphalein and formol titration procedures were sufficiently well correlated with those of the Farinograph to give a good estimate of protease activity in dough.

D. Harvey.

NAFFZIGER, T. R. and MAHON, H. I. **Feed evaluation, determination of absorption capacity and fibrous material of pith and certain feed constituents.** *J. Agric. Food Chem.*, 1953, **1**, 847-851. [N. Reg. Res. Lab., Peoria, Ill.]

In a search for materials of high absorption capacity for use to hold molasses in mixed feeds, the following techniques were adopted. The term fibre does not mean crude fibre as ordinarily estimated but refers to material of elongated fibrous physical character. Materials were conditioned at 73° F. and 50 per cent. relative humidity for 16 hr. before use and then 3-g. samples were made into pellets by compression at 15,000 lb. per sq. in. Their absorption capacity for water and the time for maximum absorption were measured in a special apparatus, which is illustrated and described. The relative amounts of fibre particles of different sizes were estimated in an apparatus consisting of 4 cascading jars with sieves of mesh ranging from 8 to 200 in successive jars. Samples of pith prepared by different methods from sugarcane bagasse and of other absorbents used in livestock feeds were examined. Sugarcane pith prepared by wet screening had an absorption capacity about 2 to 3 times that of the commercial feed ingredients tested. Particle size affected both absorption capacity and pelleting characteristics.

1566

MORRISON, S. D. A method for the calculation of metabolic water. *J. Physiol.*, 1953, 122, 399-402. [Inst. Physiol., Univ. Glasgow.]

It was found possible to calculate metabolic water from respiratory metabolism data, with the equation

Metabolic water formed (g.) = $0.1998 \times \text{Litres } O_2 \text{ consumed} + 0.4692 \times \text{Litres } CO_2 \text{ produced} - 0.9700 \times \text{g. Urinary N.}$

By substituting some standard values, several convenient working equations are reached for estimation of metabolic water from total energy production. Experimental conditions affecting the validity of the equations are discussed.

D. Duncan.

1567

DENTON, A. E., GERSHOFF, S. N. and ELVEHJEM, C. A. A new method for cannulating the portal vein of dogs. *J. Biol. Chem.*, 1953, 204, 731-735. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The method consisted in the introduction into the portal vein, at a point about 1 in. from the liver, of a length of silicone-coated fine plastic tubing, "Geneflex" tubing, the other end of the tube being brought by a subcutaneous path to the exterior at a point behind the shoulder. Here it was filled with saline, tied off, and secured to the skin. Operative details are given.

Such a cannula has remained functioning for 6 to 8 weeks. Through it 10-ml. samples of portal vein blood were withdrawn, and 10 amino-acids were estimated in the plasma. Comparison of the results with those of contemporary samples from the radial vein showed that a much greater increase of amino-acid concentration could be detected in the portal vein than in the radial vein at different times after ingestion of a meal.—W. A. Greig.

CASTER, W. O., SIMON, A. B. and ARMSTRONG, W. D. A direct method for the determination of Evans Blue using zephiran as a solvent. *J. Lab. Clin. Med.*, 1953, 42, 493-498. [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

Vol. 24, No. 2

Fresh heparinised plasma (20 μ l.) in a spectrophotometer cell is treated with a 12.8 per cent. solution of zephiran chloride and mixed, and the optical density of the mixture is measured. Most errors due to fat in the plasma are eliminated and those due to haemolysis can be corrected for by a formula given.—H. G. Bray.

1570

ROBERTS, L. N., SMILEY, J. R., SEARS, G. A. and MANNING, G. W. Plasma volume, measured by iodinated albumin, and T-1824. *Canad. Med. Assoc. J.*, 1953, 69, 510-519. [Dept. Med., Univ. W. Ontario, London.]

From the results of a comparative study of the 2 techniques it is concluded that the Evans Blue method should not be used for serial estimations. The radio-active iodinated human albumin method is simpler for clinical use.—H. G. Bray.

1571

ERICKSON, J. R., MCCORMICK, J. B. and SEED, L. An improved method for the determination of blood volume using radioactive iodinated human serum albumen. *Science*, 1953, 118, 595-596. [Isotope Lab., Augustana Hosp., Chicago, Ill.]

A simple procedure is described, which is safe and gives reproducible results for samples taken at short intervals.—H. G. Bray.

1572

FRANK, H. and GRAY, S. J. The determination of plasma volume in man with radioactive chromic chloride. *J. Clin. Invest.*, 1953, 32, 991-999. [Biophys. Lab., Harvard Med. Sch., Boston, Mass.]

The method described involves the injection of a solution of chromic chloride labelled with ^{51}Cr . This is bound to plasma proteins and after 5 min. samples of blood are withdrawn and their isotope concentration is measured with a suitable counter. The method is accurate to within 3 per cent. as compared with haemorrhage and transfusion experiments with known volumes of plasma.

For 21 adult males the mean circulating plasma volume was $2894 \text{ ml.} \pm 366$, the mean plasma volume per kg. $39.3 \text{ ml.} \pm 4.9$ and the mean plasma volume per sq. m. surface area $1515 \text{ ml.} \pm 157$. The principles of the estimation of ^{51}Cr are discussed.—H. G. Bray.

1573

GRAY, S. J. and FRANK, H. The simultaneous determination of red cell mass and plasma volume in man with radioactive sodium chromate and chromic chloride. *J. Clin. Invest.*, 1953, 32, 1000-1004. [Biophys. Lab., Harvard Med. Sch., Boston, Mass.]

The subject's red cells are labelled *in vitro* with sodium chromate containing ^{51}Cr and the plasma proteins with injected labelled chromic chloride as described in the preceding Abst. The radioactivity of cells and plasma in samples of blood collected after about 5 min. are then measured.

DAVIS, F. E., KENYON, K. and KIRK, J. **A rapid titrimetric method for determining the water content of human blood.** *Science*, 1953, 118,

276-277. [Dept. Pathol., Sch. Med., Univ. S. California.]

The titrimetric method of estimating water with the Karl Fischer reagent either by direct titration or by an electrometric end-point gave results for water in whole blood or plasma within about 1 per cent. of those obtained by oven drying. The estimation takes only 10 min. and requires 1 drop of capillary blood.

From a series of 100 samples from unselected blood donors the average percentage value for water in whole blood was 80.8 for females and 80.4 for males. In a smaller group of 15 samples the average values were 80.5 per cent. for whole blood water, 92.5 per cent. for plasma water and 66 per cent. for cellular water.—W. Godden.

O'NEIL, J. B. and SPINKS, J. W. T. **A simple method for determining percent uptake of Ca^{45} in tibiae of chicks.** *Poultry Sci.*, 1953, 32, 877-878. [Dept. Poultry, Univ. Saskatchewan, Saskatoon.]

Triplicate groups of 10 New Hampshire \times Barred Plymouth Rock chicks were given an adequate ration alone or with sufficient added vitamin D in maize oil to supply 9, 15, 19.4 and 25 I.U. per 100 g. feed. At 15 days of age all chicks received an oral dose of 0.5 mg. ^{45}Ca as 0.5 ml. CaCl_2 with an activity of approximately 1 μC . per dose. The left tibia of each bird in the group was removed 48 hr. later, dried and ground and compressed into 2.5 g. briquettes of diameter 3 cm. The activity of these briquettes was estimated by scanning from either side with an end window Geiger counter. The briquettes were then ashed and the Ca was recovered as oxalate, the activity of which was similarly estimated. No difference was found in ^{45}Ca uptake of the bone as measured by these methods, a highly significant correlation of +0.9662 existing between the series of measurements. The variation of the replicates of any estimation was similar for both methods.

The ^{45}Ca uptake of the bone was found in 1½ hr. by the new method reported, compared with 8 hr. for the conventional Ca oxalate technique.

MAINLAND, D. (with MAINLAND, R. B.) **Evaluation of the skeletal age method of estimating children's development. 1. Systematic errors in the assessment of roentgenograms.** *Pediatrics*, 1953, **12**, 114-129. [Dept. Anat., Dalhousie Univ., N.S.] Spanish summary.

The systematic error in skeletal assessment is defined as the persistent difference between an observer's assessments and those of the same X-ray photographs by an expert. The systematic error of an untrained observer was studied by comparing her assessment of the X-ray photographs of the hand in Macy's *Nutrition and Chemical Growth in Childhood* with the published assessments of the same photographs by experts. The assessments of experts as published in Todd's atlas and that of Greulich and Pyle were also compared. It is concluded that even expert assessment of skeletal maturation has not yet reached a desirable degree of stability.—D. Duncan.

LAGIER, R. and DEMOLE, M. **Les difficultés techniques du bilan azoté chez l'homme. L'importance du régime antérieur. [Technical difficulties in ascertaining nitrogen balance in man. Importance of the pre-experimental regimen.]** *Presse méd.*, 1953, **61**, 1399-1401. [Fac. Méd., Geneva.]

The need is stressed for consideration of both physical and psychological details in the selection of subjects and of the duration of balance experiments. The preliminary period should be varied according to the subject's history, but always long enough to allow complete adaptation to the experimental diet and the establishment of a steady state before the experiment proper is begun. Constant clinical supervision is desirable to ensure the absence of "stress" which might affect the N balance.—D. Duncan.

BALZER, E. and WERNER, K. **Eine für die Pankreasfunktionsprüfung geeignete Methode zur** Vol. 24, No. 2

Bestimmung der stärkeverzuckernden Fermente im Duodenalinhalt. [Method of estimating the starch-hydrolysing enzymes of duodenal juice, suitable for testing pancreas function.] *Gastroenterologia*, 1953, **80**, 211-220. [Klin. Med., Univ. Münster.] English and French summaries.

In this method, which is suitable for routine clinical work, the starch-hydrolysing enzymes of the duodenal contents are estimated by digesting a 25 per cent. starch solution at 38° C. with 0.5 ml. of undiluted duodenal juice. The reducing power of the starch-degradation products formed by the hydrolysing enzymes of the juice is measured by estimating the aldehyde groups with hypiodite and expressing the results as glucose. The procedure covers a range from 0 to 1300 mg. glucose. For normal persons the range found was 540 to 900 mg. glucose. Thus the method allows a larger range for decrease of enzyme activity, which is more important diagnostically, than for its increase. The usefulness of the method for testing external pancreatic secretion is illustrated by enzyme curves obtained from fractional estimations on duodenal juice in healthy subjects and in patients with pancreatic disease.—M. B. Richards.

CARPENTER, K. J. **The concept of an "appetite quotient" for the interpretation of ad libitum feeding experiments.** *J. Nutrition*, 1953, **51**, 435-440. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

In order to eliminate the effects of difference in food intakes between groups of animals fed to appetite on different experimental diets a method of mathematical treatment of results is suggested. The "same level of food intake" is interpreted as such that "the rate of intake of metabolizable energy is the same proportion to bodyweight^{0.88}". An example is calculated from the data of an experiment of Laguna and Carpenter (Abst. 4804, Vol. 21), to demonstrate that observed differences in growth between groups of rats on nicotinic-acid-deficient and supplemented diets were not to be explained by differences in appetite.—D. Duncan.

1585

BRAY, D. J., SANFORD, P. E. and CLEGG, R. E. **The value of paired individual comparisons in chick growth experiments.** *Poultry Sci.*, 1953,

32, 1094-1095. [Kansas Agric. Exp. Stat., Manhattan.]

In a feeding trial chicks were fed from one day to 12 days of age on a depletion ration; they were then stratified according to their weight gain over this period with 6 chicks in each stratum. One chick from each stratum was then given each of the 6 experimental treatments: altogether 6 strata were used. Each chick was caged individually, and the experiment continued for 23 days.

Statistical analysis taking into account the variance eliminated by stratification greatly increased the sensitivity of the test for the detection of treatment differences. The same result was obtained in a further trial of similar design, and it is concluded that this experimental technique is of considerable value for work with expensive

rations where it is important to use the minimum number of experimental animals.—K. J. Carpenter.

WHITE, G. D. Weight loss in stored wheat caused by insect feeding. *J. Econ. Entomol.*, 1953, **46**, 609–610. [U.S. Dept. Agric., Agric. Res. Admin., Bur. Entomol.]

Fifteen sub-samples each weighing about 14 g. were taken from a sample of newly harvested

wheat that had been freed from living insects by exposure to a temperature below freezing-point for 5 days.

To each of 10 sub-samples, 20 adult female rice weevils, from 2 to 3 weeks old, were introduced; the remaining 5 sub-samples acted as controls. All were kept at 80° F. and 70 per cent. relative humidity. The weevils were allowed to oviposit for 2 days and were then removed. One week later, and weekly thereafter, all the samples were weighed. Gain or loss in the controls was due to variations in moisture content and the correction was applied to the test samples. Emergence of adult weevils began after 4 weeks and was complete by the end of the fifth week. Weevils were removed daily, as only losses due to developing larvae were being measured.

The mean losses of weight per infested kernel at the end of each of 5 weeks were, in per cent., 0.67, 2.36, 6.52, 13.59 and 20.00. The weight of refuse such as faecal matter, moulted skins, pupal cases and frass left within the kernels was not estimated, so that the actual loss of endosperm was greater than the weight losses indicated. About 68 per cent. of the total loss of weight occurred during the first 4 weeks of development when there was no outward sign of infestation.—P. C. Jowsey.

- NICHOLAS, J. E., PERRY, J. S., GAREY, J. G., MURPHY, J. F., GUERRANT, N. B., HARTZLER, E. R., DODDS, M. L. and BENNETT, G. **Some factors affecting the quality of frozen foods.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 565, April 1953, pp. 29. [State College, Pa.]

The foods studied were beef, pork, peas and Lima beans obtained during two seasons. They were frozen, in packed or unpacked states, in still air at 0° F. or in air blast at -20° F. and stored at +10°, 0° or -20° F. Details of the preparation of the foods are given.

During refrigeration wide differences were found between packed and unpacked samples for the times taken to pass the second stage, that of maximum crystal formation. Bacteriological examinations showed that the type of food had no effect on the results obtained and that the conditions of storage which showed the highest survival rate for organisms were those which gave products subsequently judged by the organoleptic panels to be of poorest quality. Biochemical studies showed

that free fatty acid and peroxide values in beef were highest in the samples stored at the highest temperature, and that loss of ascorbic acid from the vegetables was greatest at the highest storage temperature. The amount of ascorbic acid lost from the beans was much less than that from peas.

It is concluded that if the quality of meat is to be maintained during storage for 4 to 8 months, the temperature of storage must be 0° F. or below and that, within the range studied, the lowest temperature provided the vegetables of the highest quality.—D. Harvey.

1610

- BASACA, M. G. **Production of yeast from molasses.** *Philippine J. Sci.*, 1952, **81**, 75-79. [Div. Biol. Res., Inst. Sci. Technol., Manila.]

Torulopsis utilis was cultivated in molasses with addition of trisodium phosphate and ammonium sulphate. The exact method is described. The average yield from 32 tests was 285 g. ground dry

yeast from 150 g. sugars of the wort. The material contained, per cent., moisture 7.5, protein 48.2, glycogen 12.5, fat 4.33 and ash 6.2. It is considered that the speed and low cost of production and the high nutritive value make it desirable that a pilot plant should be set up in the Philippines.

Available molybdenum was estimated in a number of foodstuffs by the method of Richert and Westerfeld (Abst. 4941, Vol. 21). When the results were compared with those for Mo estimated chemically it was found that from 50 to 100 per cent. of the total Mo in the foodstuffs was available. Legumes, cereal grains, some dark green leafy vegetables and liver, kidney and spleen were good sources of Mo as xanthine oxidase factor. Fruits, berries and most root and stem vegetables were relatively poor sources.—W. Godden.

FREIMUTH, U. Studien über die Eiweisskörper des Milchserums. 2. Koagulation durch Erhitzen. [The proteins of whey. 2. Coagulation by heat.] *Biochem. Ztschr.*, 1953, **324**, 504-511. [Inst. Tierzuchtforsch., Deutsch. Akad. Landwirtschaft., Berlin.]

For part 1 see Abst. 1463, Vol. 24.

Albumin and globulin were salted out from milk serum with Na_2SO_4 and were separately coagulated by heat in acetate buffer solutions of different concentration and pH. There was no characteristic difference in the behaviour of proteins from cow, ewe and goat milks. Neither protein showed complete coagulation; in both the maximum was attained at pH 4.5. The curve for albumin was symmetrical about this point, but that for globulin remained horizontal from pH 4.5 to the neutral point. The curves were not affected by changes in the molar concentration of the buffer solutions. The proteose fraction, not coagulable by heat, depended on the pH and also on the protein concentration, owing probably to dissociation of the protein molecule by denaturation and splitting of the peptide chain.—W. Godden.

1623

PATTON, S. The presence of hippuric acid in milk. *J. Dairy Sci.*, 1953, **36**, 943-947. [Dept. Dairy Husb., Pennsylvania Agric. Exp. Stat., State College.]

Hippuric acid was estimated in skimmed milk by digestion of the milk with trypsin, acidification with H_2SO_4 and continuous extraction with ethyl ether. The N estimated in the extract by the Kjeldahl method was a measure of the hippuric acid in the skimmed milk. The values for 14 samples analysed over a period of 6 months were 3.1 to 6.4, average 5.1 mg. per 100 ml., values considerably higher than those previously reported by Karabinos and Dittmer (Abst. 1949, Vol. 13). W. Godden.

MORTON, R. K. Alkaline phosphatase of milk. 1. Association of the enzyme with a particulate lipoprotein complex. 2. Purification of the enzyme. *Biochem. J.*, 1953, **55**, 786-795; 795-800. [Dept. Biochem., Univ. Cambridge.]

1. Alkaline phosphatase, which is low in milk, is largely adsorbed on the fat globules, from which it can be released into the aqueous phase by churning the cream. The butterfat is devoid of activity. The enzyme is present in fat-free separated milk as a particulate lipoprotein complex and can be sedimented along with a portion of the casein by high-speed centrifuging. The lipoprotein particles are also precipitated along with casein by acids, salts or organic solvents, but the use of rennin or pepsin permits of some separation. The

lipoprotein complex which binds the milk alkaline phosphatase may be disrupted by treatment of the aqueous material, i.e., milk or its products, with *n*- or isobutanol. This removes the lipid and leaves the enzyme in true solution.

2. With butanol to disrupt the lipoprotein complex, by centrifuging the solution, the alkaline phosphatase was purified to an activity 5600 times that in the initial whole milk, the final product having an activity of 15,300 units per mg. N. A unit is defined as the amount of enzyme which liberates 1 μg . inorganic P per min. from sodium β -glycerophosphate at 38° C. Electrophoretic studies indicated that the purified enzyme was probably homogeneous. In the course of the purification a red protein fraction was separated from buttermilk, but its identity was not established.—W. Godden.

1625

DAVIDOV, R. and ANISIMOVA, V. Soderzhanie ioda v moloche. [Iodine content of milk.] *Mol. Prom.*, 1953, **14**, No. 8, 33-35. [Sel.-Khoz. Akad. Im. Timiryazeva, Moscow.]

The I content of milk was estimated at different periods of lactation. Taking the average I content of the colostrum as 100 per cent., the I content of the milk during the main period of lactation was 40 and at the end of lactation 21 per cent. The I content in winter was $1\frac{1}{2}$ times that in summer. Milk that had been pasteurised, cooled and stored contained 22 per cent. less I than raw milk.

BRUNNER, J. R., DUNCAN, C. W. and TROUT, G. M. The fat-globule membrane of non-homogenized and homogenized milk. 1. The isolation and amino acid composition of the fat-membrane proteins.

BRUNNER, J. R., LILLEVIK, H. A., TROUT, G. M. and DUNCAN, C. W. 2. Differences in the electrophoretic patterns of the fat-membrane proteins.

BRUNNER, J. R., DUNCAN, C. W., TROUT, G. M. and MACKENZIE, M. 3. Differences in the sedimentation diagrams of the fat-membrane proteins. *Food Res.*, 1953, **18**, 454-462; 463-468; 469-474. [Dept. Dairy and Agric. Chem., Michigan Agric. Exp. Stat., East Lansing.]

1. The proteins of the fat globule membrane of homogenised and non-homogenised milk were isolated from the separated cream by removing the fat as butter, concentrating the serum, dialysing, treating the non-dialysable material with ethanol and ethyl ether, dispersing the residue in water and lyophilising. Thirteen amino-acids and N were estimated in the resulting preparations. The membrane proteins from the homogenised

milk had higher concentrations of glutamic acid and lysine and lower concentrations of cystine, glycine and tryptophan than had the membrane proteins from non-homogenised milk. The results indicated that the main protein constituents of the milk plasma form a large percentage of the membrane protein complex in homogenised milk.

2. Ascending and descending mobility patterns were obtained for the fat membrane proteins from the two types of milk in different buffer systems from pH 1.5 to 10.8. The number of components differed in the two types of membrane protein. The components were not identified, but the results support the view that the membrane proteins from homogenised milk contain adsorbed milk plasma proteins.

3. The ultracentrifugal sedimentation velocity diagrams of the two types of fat membrane proteins support the above findings.—W. Godden.

1627

CONOCHIE, J. **Indole and skatole in the milk of the ruminant feeding on *Lepidium* spp.** *Austral. J. Exp. Biol. Med. Sci.*, 1953, **31**, 373-384. [Dairy Res. Sect., C.S.I.R.O., Melbourne.]

The high indole content of butterfat from cows feeding on *Lepidium virginicum* was reported by Hussong and Quam (Abst. 1768, Vol. 13). At times *Lepidium hyssopifolium* provides the greater part of the herbage available to dairy stock in southern Queensland. It was shown that under such conditions the taint in milk is due to the presence of indole and skatole, although the plant contains no abnormal amount of any known precursor of indole. Strained rumen contents from sheep were incubated alone or with *Lepidium*. No difference in indole production was observed. The feeding of antibiotics eliminated *Bacterium coli* from the faeces and reduced but did not prevent the abnormal concentrations of indole and skatole in the milk. In experiments with goats given *Lepidium* there was no significant increase in the daily urinary indican excretion or in the indole output in faeces, but when hourly collections of urine were taken there was evidence of a temporary interference with the detoxification of indole which could account for the high indole level in the milk. When the animals were changed from an alfalfa to a *Lepidium* diet indole in the blood rose from zero to 1.0 p.p.m. and such a high level at the time of milking caused a high concentration in the milk fat. The results did not indicate any practicable means of reducing the incidence of *Lepidium* taint in milk (cf. Conochie, *Austral. J. Dairy Technol.*, 1950, **5**, 43.)

HANSEN, R. P. and SHORLAND, F. B. **The branched-chain fatty acids of butterfat. 3. Further investigations on a multibranched C₂₀ saturated fatty acid fraction.** *Biochem. J.*, 1953, **55**, 662-663. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

With the combined techniques of fractional distillation *in vacuo*, chromatography on activated alumina and low-temperature crystallisation, a multi-branched C₂₀ saturated fatty acid fraction was isolated from 36.7 kg. of New Zealand butterfat. The amount, 0.006 per cent. of the butterfat, probably represented only a part of the total.

In a previous paper (Abst. 231, Vol. 22) the isolation of a similar fraction from butterfat was reported, but in this earlier work one of the isolation techniques involved hydrogenation; the present work established that the C₂₀ acid fraction exists naturally, in part or in whole, as a saturated constituent.—G. A. Garton.

1630

CORNWELL, D. G., BACKDERF, R., WILSON, C. L. and BROWN, J. B. **The trans-octadecenoic acid content of butterfat.** *Arch. Biochem. Biophys.*, 1953, **46**, 364-375. [Inst. Nutrit. Food Technol., Columbus, Ohio.]

Methyl esters of the fatty acids of 3 samples of summer butterfat from Jersey cows and from 1 sample of winter butterfat from a mixed herd were prepared. The mixed esters were distilled *in vacuo* to yield concentrates of the C₁₈ esters, which were further concentrated by low-temperature crystallisation, from appropriate solvents, of the esters or the free acids. The fractions were examined for the presence of *trans* fatty acids by infrared absorption analysis.

The 3 summer butterfats contained from 9.5 to 9.7 per cent. of *trans* fatty acids, mainly *trans*-octadecenoic and -octadecadienoic acids; traces of other *trans*polyethenoid acids may have been present. The winter butterfat contained 5 per cent. of *trans* acids. Of the "oleic" acid of summer butterfat, 14 to 20 per cent. was identified as *trans* isomers, one component of which was probably vaccenic acid. *Trans*-octadecadienoic acids accounted for 6 to 8 per cent. of the total fatty acids of summer and 3.5 per cent. of those of winter butterfat.—G. A. Garton.

LALITHA, K. R. and DASTUR, N. N. **Keeping quality of ghee. 1. Effect of nature of milk, method of preparation, temperature of melting and antioxidants on the keeping quality.** *Indian J. Dairy Sci.*, 1953, **6**, 147-168. [Indian Dairy Res. Inst., Bangalore.]

Samples of ghee prepared from cow and buffalo milk under different conditions by the desi and creamery methods were stored for up to 184 days and sampled at intervals. The results are given in detail.

Butterfat prepared at 40°, 65° and 115° C. kept well provided that moisture and impurities were removed. Peroxides developed more slowly in the 40° C. sample than in the others. An off-flavour became perceptible at a peroxide value of about 1.0 and was pronounced at a value of 1.5. Ghee made by the desi method developed peroxides faster than creamery ghee.

Small amounts of free fatty acids, up to 1.5 per cent. oleic acid, did not affect keeping quality. High-acid ghee spoiled rapidly. Ethyl gallate added at a concentration of 0.02 per cent. checked oxidative spoilage but had no effect on the development of free fatty acids.—P. C. Jowsey.

Eggs

1635

EVANS, R. J. and DAVIDSON, J. A. **The protein content of fresh and stored shell eggs.** *Poultry Sci.*, 1953, **32**, 1088-1089. [Dept. Agric. Chem., Michigan State Coll., East Lansing.]

Three lots each of 64 eggs from Single Comb White Leghorn hens were used. One lot was examined as soon as possible after laying and the

others after storage at 0° C. for 9 and 18 months. N was estimated in yolk and whites separately.

The following protein (N × 6.25) contents were found in fresh, 9-month-old and 18-month-old eggs, respectively: white 3.11, 3.24, 2.92; yolk 2.79, 2.74, 2.91 mg. per egg. The loss of protein over 18 months was considered to be insignificant.

A loss of 13.9 per cent. after 18 months' storage reported previously (Abst. 225, Vol. 19) is now thought to have been due to differences in the protein contents of the initial samples.

P. C. Jowsey.

Meat (All Kinds)

1636

ALEXANDER, J. C., BECKNER, C. W. and ELVEHJEM, C. A. **The alanine, cystine, glycine and serine content of meat.** *J. Nutrition*, 1953, **51**, 319-328. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The meat samples were the same as those used by Violante *et al.* (Abst. 192, Vol. 23). The amino-acids were estimated microbiologically. Results are given in detail.

Average values for all samples were: cystine 1.1, glycine 5.0, serine 5.2, alanine 6.4 g. per 100 g. protein calculated to 16 per cent. N.

Tween 80 at a level of 0.005 per cent. by volume was added to all assay media. It had the effect of eliminating a lag from the alanine standard curve and reduced blank titration values, removed the depression of growth for *Leuconostoc mesenteroides* at higher levels of cystine, eliminated drifts with *Lactobacillus casei* in serine assays and increased the recovery of serine with *Lactobacillus delbrueckii* from 94 to 98 per cent. It also produced a general stabilising effect in all assays, resulting in less variation and greater reproducibility of results.

SAHA, K. C. and CHOWDHURY, N. K. **Nutritional investigations on the sun-dried fish of West Bengal.** *Ann. Biochem. Exp. Med.*, 1951, **11**, 193-196. [Technol. Lab., Directorate Fish., Govt. W. Bengal.]

Samples of sun-dried fish from a new government curing factory were compared with samples bought from local curers who use primitive traditional methods. The factory samples had consistently higher protein and much lower ash contents. About 75 per cent. of the ash in locally cured samples was sand, some picked up during the drying process and some deliberately added to increase the weight. The local samples carried a greater number of bacteria than the factory samples.—P. C. Jowsey.

CONNELL, J. J. **Studies on the proteins of fish skeletal muscle. 2. Electrophoretic analysis of low ionic strength extracts of several species of fish.** *Biochem. J.*, 1953, **55**, 378-388. [D.S.I.R., Torry Res. Stat., Aberdeen.]

With the technique previously reported (Title 4041, Vol. 23), muscle extracts of 20 species of fish were examined electrophoretically at 0.05 I, pH 7.5. Each species had a characteristic electrophoretic diagram and there were considerable differences between them in mobility and composition. The diagrams of related species appeared to be as dissimilar as those of unrelated species. The diagrams could, however, be divided into 3 definite mobility groups. Elasmobranch muscle appeared to contain proteins with unusually high isoelectric points. The effect of age and of species variants on the diagrams was examined.

W. Godden.

1641

SAHA, K. C., SEN, D. P. and SEN, H. K. **Studies on the keeping quality of fish meal used as poultry food.** *Ann. Biochem. Exp. Med.*, 1951, **11**, 197-202. [Technol. Lab., Directorate Fish., Govt. W. Bengal.]

Fishmeal prepared from mixed waste fish was stored for about 6 months at room temperature and humidity in gunny sacks holding 20 lb. or in stoppered glass jars holding 10 lb. Samples were taken every 15 days and moisture, N and protein were estimated and bacterial count was recorded. Fortnightly averages of temperature and humidity

were ascertained also. The results are given in detail.

The meal stored in sacks deteriorated most rapidly. The moisture content rose steadily over the first 10 weeks from about 8 to 18 per cent. and the condition of the meal became favourable to the growth of bacteria, fungi and insects. The bacterial count, though fluctuating, showed a general increase from approximately 30,000 to nearly 60,000 per g. over 10 weeks and remained generally high for the rest of the test. Protein decreased from 39.4 to 27.0 per cent. on a dry matter basis over 6 months.

The moisture content of the meal stored in jars also increased, but more slowly. From an initial value of 8.4 it rose to 13.6 per cent. over 6 months. Over the same period protein fell from 42.7 to 36.9 per cent. The bacterial count fluctuated violently but at the end of 6 months was approximately the same as at the start.

For about 8 weeks the physical characteristics of both sets of samples were similar, but thereafter the meal in sacks deteriorated in texture and developed an unpleasant smell. No such change occurred in the meal stored in glass.

P. C. Jowsey.

1642

LOVERN, J. A. and OLLEY, J. **The lipids of fish. 4. The lipids extracted by an ethanol : ether mixture from haddock flesh previously extracted with acetone.** *Biochem. J.*, 1953, **55**, 686-696. [D.S.I.R., Torry Res. Stat., Aberdeen.]

The lipid fraction examined was that referred to in the first of this series of papers (Abst. 4042, Vol. 23). The crude ethanol : ether extract was completely soluble in light petroleum, but nevertheless it contained more than 50 per cent. of non-lipid impurities which were largely removed by the method of Folch *et al.* (*J. Biol. Chem.*, 1951, **191**, 833). The purified lipid was separated by counter-current distribution between light petroleum and 85 per cent. ethanol into lecithin, phosphatidylethanolamine, plasmalogens, waxes, hydrocarbons and inositol lipids, and some unidentified material.—G. A. Garton.

DUCHÂTEAU, G., FLORKIN, M. and THWIN, N. **Acides aminés non protéiniques d'un échantillon de "ngapi seinsa". [Non-protein amino acids in a sample of "ngapi seinsa".]** *Bull. Soc. Chim. biol.*, 1953, **35**, 1149-1151. [Lab. Biochim., Univ. Liège.]

"Ngapi seinsa" is a paste made in Burma from sun-dried, ground, salted shrimps. The paste is compressed into jars and covered with salt. After

6 months, during which time liquid is poured off and renewed from time to time, the paste is ready for use in cooking. A sample contained 270 g. NaCl and 25.5 g. dialysable N per kg. Of this dialysable N, 73.2 per cent. was accounted for as 15 amino-acids.—W. Godden.

FOODSTUFFS OF VEGETABLE ORIGIN

General

1644

CAMARA-BESA, S. F. and BATACLAN, M. **The sodium and potassium content of Philippine foods. 1. Foods of plant origin.** *Acta med. philip.*, 1952, 9, 1-30. [Dept. Physiol. Biochem., Coll. Med., Univ. Philippines.]

Details are given of methods of sampling and preparation of common fruits, vegetables and processed vegetable products for analysis by flame photometry. The Na and K contents of 218 different foods are listed with the native, English and scientific names of the plants of origin. A second table gives the Na and K contents of water samples from local supplies to assist dietitians in making up diets of low Na content. The foods examined had low Na contents, mostly below 10 mg. per 100 g. edible portion. The K contents were generally high and exceeded 1 per cent. in some samples.

The values are of the same order of magnitude as those reported from the United States for similar foods.—A. M. Copping.

1645

NOONAN, J. B. **Molybdenum deficiency in maize and other crops in the Taree district.** *Agric. Gaz. N.S.W.*, 64, 422-424.

1646

MCLACHLAN, K. D. **Phosphorus, sulphur and molybdenum deficiencies on some soils of the Northern Territory.** *J. Austral. Inst. Agric. Sci.*, 1953, 19, 197-199. [Div. Plant Indust., C.S.I.R.O., Canberra.]

Subterranean clover plants grown in pots in grey, red, limestone or granitic soil were treated with P, S and Mo fertilisers in all combinations in an experiment of randomised block design. Significant yield responses to P were obtained on all 4 soils. Response to S was significant on all soils except granitic and significant responses to Mo were obtained on red and granitic soils. The grey, red and limestone soils were more severely deficient in P than eastern Australian soils formed on similar parental material. The S and Mo deficiencies were of the same order as those found in soils of eastern Australia.—F. C. Aitken.

1647

MINKH, A. A. **Ftor v pishchevykh produktakh. [Fluorine in food.]** *Stomatologiya*, 1953, No. 2, 5-8. [Kaf. Gigieny, Med. Stomatol. Inst., Moscow.]

F was estimated in cereals and vegetables grown in different parts of the U.S.S.R. The F content of cereals such as rye, wheat, barley and buckwheat lay within the limits of 0.14 to 0.36 mg. per cent. No great difference was detected between the F contents of the same cereal from different areas. Fairly large variations were found in the F contents of different samples of buckwheat and oats grown in the same area. The F content of vegetables such as beet, cabbage, potatoes, carrots and turnips ranged from 0.02 to 0.95 mg. per cent. Using Gabovich's results for products of animal origin it was estimated that a man probably ingests up to 1 mg. F daily in food.—W. Hughes.

1648

BRANDT, E., PINDBORG, E., FREDSTED, I. and HOFF-JØRGENSEN, E. **Undersøgelser af oxalsyreindholdet i levnedsmidler. [Oxalic acid in foods.]** *Staten Husholdningsråds Faglige Meddelelser*, 1953, No. 4, 19-26.

The toxic effects of oxalic acid caused by the precipitation of Ca in the intestine or within the body are discussed. Data are presented for oxalic acid, estimated by titration with ceric sulphate after extraction with HCl and then ether, in 27 varieties of summer spinach and 25 varieties of spring spinach, for Ca in 8 varieties, for oxalic acid in large- and small-leaved plants of the same kind, and for the loss of oxalic acid when spinach is boiled in small and large amounts of water. On the average of all varieties and places in 1951 and 1952 oxalic acid varied between 665 and 822 mg. per 100 g. fresh weight and none was outstandingly low. Small-leaved plants had less than large-leaved, small-leaved Juliane least with 460 mg. Five per cent. more was lost in boiling with much water than with little.

Oxalic acid in the stalks of all varieties of rhubarb varied from 210, 150 and 100 mg. in the bottom, middle and top third of thin stalks of the variety Linnæus to 890, 620 and 470 mg. in the variety Elmsfeuer. The latter was judged the best rhubarb on taste and colour. Rejection of the bottom third of any variety would greatly reduce the total oxalic acid.

Oxalic acid in teas varied from 970 to 1280 mg. per 100 g. but 100 ml. boiled water had, on the average, enough Ca to fix the oxalic acid in 1 g. tea. Cocoa contained about 500 mg. which, in the quantities used in cocoa made with milk, was also negligible. Other values given are, in mg. per 100 g.: elderberries 12 and 15, beet 710 and 800;

parsley 165 and 170 ; dill 140 and 150 ; tomato 0, 0 and 5 in 3 samples.

If, for instance, rhubarb of the Elmsfeuer-type is to be used, the addition of 2 dessertspoonfuls of a 40 per cent. solution of calcium chloride is recommended, or 1 dessertspoonful for the varieties with less oxalic acid.—I. Leitch.

1649

NYE, P. H. **A survey of the value of fertilizers to the food-farming areas of the Gold Coast. 1. Aims and methods of the survey.** *Empire J. Exp. Agric.*, 1953, **21**, 176-183. [Dept. Soil Sci., Univ. Coll., Ibadan.]

Twelve areas totalling 10,245 sq. miles and comprising about 1/9 of the total area of the Gold Coast were surveyed. Trial crops included early and late millet, guinea corn, groundnuts, maize, rice and yams. In each of the 12 areas, 30 sites were selected at random for each crop under trial and at each site a single replication of a 3 × 3 design was laid down with all combinations of the following treatments: sulphate of ammonia 0, 60 or 120 lb. per acre ; superphosphate (18.5 per cent. water-soluble P_2O_5) 0.60 or 120 lb. per acre. Groundnuts trials comprised 3 plots only and no N fertiliser was applied.

Results will be reported in subsequent papers.

P. C. Jowsey.

Cereals

1650

HALVERSON, A. W. and OLSON, O. E. **The protein composition of barley grown in South Dakota.** *S. Dakota Agric. Exp. Stat. Tech. Bull.* No. 13, January 1953, pp. 18.

The barley varieties Feebar, Odessa and Plains were grown on adjacent plots at 5 stations during 1950 and 1951.

In the first year Feebar and Odessa samples were ground in a Wiley mill, a hammer mill and a ball mill to estimate the effect of fineness of grinding on protein fractionation data. The methods are described. The hammer-milled samples gave the most complete separation of fractions and the most consistent results.

The N content of the barley samples ranged from 1.75 to 3.10 per cent. of the dry matter (protein from 10.9 to 19.4 per cent.). Salt-soluble N, hordein N and glutelin N were estimated and the results are presented in detail. In all 3 varieties glutelin N and hordein N increased as the total protein increased ; salt-soluble N remained almost constant. Expressed as a percentage of total N, glutelin N remained fairly constant, hordein N increased and salt-soluble N decreased as total protein increased.

Vol. 24, No. 2

It was concluded that the protein composition of barley can be forecast with reasonable accuracy if the total protein content is known.—P. C. Jowsey.

1651

HINTON, J. J. C. **The distribution of protein in the maize kernel in comparison with that in wheat.** *Cereal Chem.*, 1953, **30**, 441-445. [Res. Assoc. British Flour-Millers, St. Albans.]

Kernels of the flinty maize variety Sibthorpe were dissected by hand, and protein ($N \times 6.25$) was estimated in the pooled fractions from several kernels. The protein contents calculated on a 14 per cent. moisture basis were, as a percentage of each fraction: pericarp 3.0, aleurone layer 19.2, endosperm 1 (outer layers) 27.7, endosperm 2 (flinty portion) 7.5, endosperm 3 (inner, floury portion) 5.6, embryo 26.5, scutellum 1.5. As percentages of the whole kernel the figures, in the same order, were: 0.2, 0.4, 1.1, 4.4, 1.0, 0.3, 1.7.

Figures for wheat obtained previously (Abst. 3219, Vol. 17) are reproduced for comparison.

In both maize and wheat, about 70 per cent. of the total protein was found in the endosperm, and there was a decreasing concentration gradient from the outer to the inner portions of this fraction.

P. C. Jowsey.

1652

SAUBERLICH, H. E., CHANG, W. Y. and SALMON, W. D. **The amino acid and protein content of corn as related to variety and nitrogen fertilization.** *J. Nutrition*, 1953, **51**, 241-250. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Nine samples (6 varieties) of maize were taken from plots which had received 24 lb. N per acre and 10 samples (10 varieties) from plots which had had 84 lb. N per acre. Protein and 18 amino-acids were estimated, the latter microbiologically.

Protein ranged from 6.8 to 8.2 per cent. in the samples from low-N plots and from 9.3 to 12.0 per cent. for those from high-N plots. The amounts of all amino-acids increased with increasing protein but the rates of increase of individual amino-acids differed considerably. N treatment increased the protein and amino-acid contents significantly and the increase was largely in the zein fraction. There was a greater proportion of zein in high- than in low-protein samples.

Other proteins increased also as indicated by an increase in tryptophan and lysine, but not in proportion to the increase in zein. It was concluded that the protein of high-protein maize was inferior to that of low-protein maize from the point of view of non-ruminant nutrition ; this should be borne in mind in the development of new maize varieties.—P. C. Jowsey.

1653

DUSTIN, J. P., SCHRAM, E., MOORE, S. and BIGWOOD, E. J. Dosage chromatographique des acides aminés d'une graine de céréale (orge), d'un foin, et d'un tourteau de lin. [Chromatographic estimation of amino-acids in a cereal grain (barley), hay and linseed cake.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1137-1147. [Lab. Biochim., Fac. Méd., Univ. Brussels.]

With the chromatographic technique previously described (see Abst. 44, Vol. 24), most of the amino-acids in the 3 feedingstuffs were estimated. Cystine, which was completely destroyed during the hydrolysis, was estimated separately by the method of Schram and Moore (in the press). Methionine was estimated as its sulphoxide and tryptophan microbiologically in an alkaline hydrolysate. The amino-acids accounted for 87.5, 78.5 and 93.9 per cent. of the total N in barley, hay and linseed cake, respectively; of the total S in barley, 84 per cent. was present as cystine and methionine; in the hay only 21 per cent. was recovered in these forms and in the linseed cake 72 per cent.—W. Godden.

1654

YEMM, E. W. and FOLKES, B. F. The amino acids of cytoplasmic and chloroplastic proteins of barley. *Biochem. J.*, 1953, **55**, 700-707. [Dept. Botany, Univ. Bristol.]

Eighteen amino-acids were estimated, most of them microbiologically, in cytoplasmic proteins from mature barley leaves and in mixed cytoplasmic and chloroplastic proteins from mature barley leaves and barley seedlings.

The contents were similar in all cases, except for lysine, which showed some slight variation.

P. C. Jowsey.

1655

GARDNER, H. W. Nitrogen top dressing of spring oats. *Agriculture, J. Minist. Agric. Engl.*, 1953, **60**, 328-334. [Hertfordshire Inst. Agric., St. Albans.]

A top-dressing of 2 cwt. Nitro-chalk per acre applied in May increased the yields of grain and straw by 1.26 and 2.0 cwt. per acre, respectively, during trials over 4 seasons with between 9 and 13 varieties of spring oats. A further similar dressing in June had little effect on either grain or straw yield and was applied principally in an attempt to increase the yield of crude protein. For 6 varieties at 3 centres over 3 seasons the following average crude protein contents of grain were found: no N 11.29, May dressing 12.41, May and June dressings 13.62 per cent. Crude protein in straw was estimated for another set of trials and averaged: no N 2.75, May dressing 3.15, May and June dressings 3.60 per cent. The

recovery of applied N was studied also and for the May dressing averaged: grain 18.0, straw 8.8 per cent. For the June dressing the recoveries were 12.9 and 6.7 per cent., respectively.

It was concluded that a June top-dressing was not justified under the conditions prevailing in Hertfordshire.—P. C. Jowsey.

1656

MARTIN, H. F. and PEERS, F. G. Oat lipase. *Biochem. J.*, 1953, **55**, 523-529. [Res. Assoc. Brit. Flour-Millers, Cereals Res. Stat., St. Albans, Herts.]

Oat lipase is located in the outer pericarp layers of the grain and was obtained from groats by the "wet-scrubbing" method of Hutchinson *et al.* (*Nature*, 1951, **167**, 758). It is a true cereal lipase, not a product of the subepidermal fungal contaminants. It was purified 2000-fold on a dry matter basis compared with the activity of the original oatmeal. The purified preparation contains 6.7 per cent. N and 0.5 per cent. P, and has an optimum pH of 7.4 and an optimum temperature of 37° to 38° C. It splits off only one butyric acid radical from tributyrin and does not hydrolyse mono- and dibutyryns at pH 7.4 and 37° C. It will not attack Crill 6, a polyoxyethylene derivative of sorbitan laurate, and is not activated by the compensatory activators required, according to Willstätter, by pancreatic lipase.—W. Godden.

1657

TEMPLETON, W. H. and CARPENTER, B. R. The lipase activity of certain cereal products. *Analyst*, 1953, **78**, 726-727. [British Baking Indust. Res. Assoc., Chorleywood, Herts.]

The lipase of the original cereal may cause off-flavour in a baked product. A modification of the method of Hutchinson and Martin (Abst. 1317, Vol. 23) was used to study the problem, and data for 10 samples of cereals are tabulated. It was found that incubation with olive oil for 6 hr. under conditions which are described was the best method of estimating the enzyme content, and that it was the grains with a high lipase content which were associated with the occurrence of off-flavours. While due consideration must be given to other circumstances, *e.g.*, the proportion of the flour used and the time elapsing between mixing and baking, it is suggested that a cereal with an activity sufficient to hydrolyse more than 1.5 per cent. of olive oil, with the method described, must be regarded as undesirable.—D. Harvey.

MCCALL, E. R., JURGENS, J. F., HOFFPAUIR, C. L., PONS, W. A. (Jr.), STARK, S. M. (Jr.), CUCULLU, A. F., HEINZELMAN, D. C., CIRINO, V. O. and

N.A. and R., April 1954

MURRAY, M. D. **Composition of rice. Influence of variety and environment on physical and chemical composition.** *J. Agric. Food Chem.*, 1953, **1**, 988-993. [S. Reg. Res. Lab., New Orleans, La.]

Eight varieties of rice were grown at 3 stations over 3 years. Samples were milled and analyses were made of hulls, true bran, endosperm and white rice.

Both variety and location had a highly significant effect on milling yield and physical composition, and also on the chemical composition of the true bran except for the ash. The N content of white rice and the ash of the hulls were significantly affected by variety; environment had a highly significant effect on the ash of the hulls and on the lipid, N, ash and starch of the endosperm.

White rice contained, on the average, 1.1 mg. total P per g., of which 46.1, 39.9, 10.3, 3.0 and 0.8 per cent. were nucleic P, phytin P, carbohydrate P, inorganic P and phosphatide P, respectively. Total P in bran amounted on the average to 26.5 mg. per g. and the fractions in the above order comprised 4.4, 89.9, 2.3, 2.5 and 1.0 per cent. of the total.

Trace elements present in all samples included Al, Cu, Fe, Mn, Ba, B and Zn.—P. C. Jowsey.

1659

FAVERO, A. **Variazioni del tenore in acido cianidrico del sorgo in rapporto all'epoca della semina e allo sviluppo della pianta. [Variations in the hydrocyanic acid of sorghum in relation to time of sowing and the stage of growth of the plant.]** *Riv. Zootec.*, 1953, **26**, 256-259. [Ist. Agronom. Gen., Univ. Milan.]

Four varieties of sorghum were investigated. In 1951 they were planted at 10-day and in 1952 at 3-weekly intervals. HCN was estimated in the top leaves of the main stem at different stages of growth: pre-bud, bud, flower half emerged and full flower. In 1952 the effect of N fertiliser was studied.

The HCN content tended to decrease with advancing state of growth. The time of sowing influenced the HCN content, but this was shown to be due to climate: increased rainfall reduced the HCN, and increased temperature just before sampling increased it. A relation was observed between the height of the plant and HCN content: at the same stage of growth the shorter varieties had more HCN than the taller. N fertiliser had no effect. Toxic levels of HCN were found in many samples, but it is pointed out that though the levels in the top leaves may be toxic, this is where there is the highest concentration, and when the whole plant is used for forage, particularly if mature, the percentage HCN may be at a safe level for stockfeeding.—T. D. Bell.

Vol. 24, No. 2

Roots

1660

CLOSE, J., ADRIAENS, E. L., MOORE, S. and BIGWOOD, E. J. **Composition en acides aminés d'hydrolysats de farine de manioc roui, variété amère. [Amino-acid composition of hydrolysates of debittered cassava flour.]** *Bull. Soc. Chim. biol.*, 1953, **35**, 985-992. [Fac. Méd., Univ. Libre, Brussels.]

A sample of cassava flour from the Belgian Congo contained 0.323, 2.23, 0.87 and 0.30 per cent. total N, crude fibre, ash and fat, respectively, on a dry matter basis. Analysis of the hydrolysate by the method of Moore and Stein (Abst. 4469, Vol. 21) indicated the presence of ornithine in relatively large amount. N in 19 acids is tabulated as percentage of the total. Glutamic acid, ornithine, alanine, aspartic acid, lysine and arginine constituted about 40 per cent., NH_3 28.7 per cent. and cystine, methionine and tryptophan 1.5 per cent. The proteins of cassava flour, as well as being small in quantity, are poor in nutritive value as indicated by the amino-acids they contain.—D. Harvey.

Leafy Vegetables

1661

ROPERTO, R., BONOLDI, V. and PRESTES MONZONI, I. **Determinação do cálcio, fósforo, ferro e cinzas em algumas hortaliças da família das Cruciferae. [Estimation of calcium, phosphorus, iron and ash in some vegetables of the family Cruciferae.]** *Rev. Fac. Med. vet., São Paulo*, 1952, **4**, 523-527. [Esc. Politéc., Univ. São Paulo, Brazil.]

Ash, Fe, Ca and P were estimated in *Brassica oleracea*, vars. *bullata*, *acephala* and *capitata*, and *Roripa nasturtium*. In 16 locally grown samples the average values for the edible portions of the vegetables, in the above order, were, in mg. per 100 g.: ash 1565, 1551, 921, 1109; Fe 5.1, 3.0, 3.4, 3.8; Ca 210.4, 260.0, 75.0, 105.9; P 48.3, 44.5, 40.2, 43.5. The Ca:P ratios were 4.3:1, 6:1, 2:1 and 2.5:1.—M. B. Richards.

1662

ROPERTO, R., BONOLDI, V. and PRESTES MONZONI, I. **Determinação do cálcio, fósforo, ferro e cinzas em algumas hortaliças da família Compositae Linn. [Estimation of calcium, phosphorus, iron and ash in some vegetables of the family Compositae, Linn.]** *Rev. Fac. Med. vet., São Paulo*, 1952, **4**, 529-532. [Esc. Politéc., Univ. São Paulo, Brazil.]

Ash, Fe, Ca and P were estimated in the edible parts of *Lactuca sativa*, *L. scariola*, *Cichorium intybus*, and *C. endiva*. For 16 locally grown samples the average values for the edible portion

of the vegetables in the above order were, in mg. per 100 g.: ash 621, 807, 1360, 949; Fe 2.7, 3.0, 7.9, 6.2; Ca 48.4, 33.6, 73.2, 35.3; P 32.2, 34.6, 35.3, 16.6. The Ca : P ratios were 1.5 : 1, 0.95 : 1, 2.1 : 1 and 2.1 : 1.—M. B. Richards.

Legumes

1663

KLIMENKO, V. G. Formy azota zerna i belkov nekotorykh sortov gorokha. [Forms of nitrogen in seeds and proteins of certain pea varieties.] *Biokhimiya*, 1953, **18**, 141-150. [Lab. Biokhim. Rast., Kishinevsk. Gosud. Univ.]

Eighteen varieties of peas were grown in the dry conditions of Moldavia and in damp conditions near the Carpathians. Seeds from peas grown under dry conditions contained considerably more total N than seeds from the same varieties grown under damp conditions. The environment also affected the protein content and its composition. An intervarietal difference was observed in protein composition. Most of the S was present as methionine. Arginine, histidine, lysine, cystine, methionine, tyrosine, and tryptophan were estimated. Data for all varieties are given in detail in tabular form.—W. Hughes.

1664

VIJAYARAGHAVAN, P. K. and SRINIVASAN, P. R. Essential amino acid composition of some common Indian pulses. *J. Nutrition*, 1953, **51**, 261-271. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Eleven amino-acids were estimated microbiologically in Bengal gram (*Cicer arietinum*), red gram (*Cajanus indicus*), green gram (*Phaseolus radiatus*), black gram (*P. mungo*), cowpea (*Vigna catjang*) and lentil (*Lens esculenta*). The results are given in detail. Limiting amino-acids were methionine, cystine and tryptophan.

P. C. Jowsey.

1665

FOWDEN, L. and DONE, J. A third unsaturated amino acid in groundnut plants: evidence for the occurrence of γ -amino- α -methylenebutyric acid. *Biochem. J.*, 1953, **55**, 548-553. [Dept. Botany, University Coll., Gower St., London, W.C.1.]

Fruits

1666

TOWNSLEY, P. M., JOSLYN, M. A. and SMIT, C. J. B. The amino acids in various tissues of citrus fruits and in orange protein. *Food Res.*, 1953, **18**, 522-531. [Dept. Food Technol., Univ. California, Berkeley.]

Amino-acids were identified chromatographically in ethanolic extracts of albedo, flavedo,

locular walls, juice vesicles, vascular tissue, seeds, navel and juice chromatophores of late Valencia and early green Washington Navel oranges, late grapefruit and tree-matured Eureka lemons.

Typical data for Valencia oranges only are presented.—P. C. Jowsey.

1667

SANTINI, R. (Jr.) Identification and determination of polybasic organic acids present in West Indian cherries (*Malpighia punicifolia* L.) and in three varieties of guava (*Psidium guajava*). *J. Agric. Univ. Puerto Rico*, 1953, **37**, 195-198. [Agric. Exp. Stat., Univ. Puerto Rico, Río Piedras.] Spanish summary.

The only polybasic organic acid found in West Indian cherries was L-malic acid, which comprised about 50 per cent. of the total acidity. Nearly all the remaining acidity was due to ascorbic and dehydroascorbic acids.

Citric acid was the main polybasic organic acid present in 3 varieties of guavas. Small amounts of tartaric, L-malic and total ascorbic acids were also present.—W. Godden.

1668

SANTINI, R. (Jr.) Determination of reducing and total sugars in West Indian cherry (*Malpighia punicifolia* L.) juice. *J. Agric. Univ. Puerto Rico*, 1953, **37**, 199-205. [Agric. Exp. Stat., Univ. Puerto Rico, Río Piedras.] Spanish summary.

Ascorbic acid in the juice of West Indian cherries interferes in the estimation of reducing and total sugars when the method of Lane and Eynon (*J. Soc. Chem. Indust.*, 1923, **42**, 325) is used. If the ascorbic acid is estimated separately and the factor 0.686 (glucose corresponding to 1 mg. ascorbic acid) is applied, the true value for the sugar is obtained. Five samples of juice contained from 3.0 to 3.6 per cent. reducing sugars or 3.0 to 3.7 per cent. total sugars. There was no appreciable loss of sugars when the juice was stored at 45° F. or at room temperature for 1 year.—W. Godden.

Other Types

1669

PONS, W. A. (Jr.), HOFFFAUR, C. L. and HOPPER, T. H. Gossypol in cottonseed. Influence of variety of cottonseed and environment. *J. Agric. Food Chem.*, 1953, **1**, 1115-1118. [S. Reg. Res. Lab., New Orleans, La.]

Seed from 8 commercial varieties of cotton grown in 13 locations during the seasons 1947 to 1949 was analysed. The range in gossypol contents, which included gossypol-like pigments, was wide, from 0.39 to 1.70 per cent. of moisture-free kernels. It may be a genetic character. High

N.A. and R., April 1954

temperatures tended to produce kernels with low, and high rainfall kernels with high gossypol contents. The effects of high temperature and high rainfall were greatest when they occurred during the period of maturation, i.e., the 35 days before boll-opening, when it is known that gossypol is synthesised. The 3 varieties with the lowest gossypol contents did not react to temperature changes in the same way as the others; with one exception there was little varietal difference in response to rainfall variation.

It is concluded that varieties with a low gossypol content might be developed and it is suggested that the ratio of N or protein to gossypol should be studied with the aim of maintaining the protein content of the meal at a high level.—D. Harvey.

1670

CRAIG, B. M. **The fatty acid composition of safflower seed oil.** *Canad. J. Technol.*, 1953, **31**, 202–207. [Prairie Reg. Lab., Nat. Res. Counc. Canada, Saskatoon, Sask.]

Safflower seed oil was methylated and fractionated by distillation.

Two samples contained 78.5 and 80.0 per cent. linoleic acid. From about 4 to 7 per cent. of palmitic, stearic and oleic acids were present and, in much smaller amounts, myristic, arachidic, behenic, hexadecenoic, eicosenoic, erucic and linolenic acids.—P. C. Jowsey.

1671

PEREIRA PINTO, G. Contribuição ao estudo químico do sêbo de ucuúba. [**Chemical study of ucuúba fat.**] *Bol. téc. Inst. agronom. Norte*, 1951, No. 23, 5–63. [Secç. Quím., Inst. Agronom. Norte, Brazil.] English summary.

More than 20 species of the genus *Virola* are indigenous to the Amazon basin, and of these *Virola surinamensis* (ucuúba branca) produces the most useful fat.

The dried seeds of this tree weigh on the average 1.8 g. and the kernel makes up 82 per cent. of this. Dried kernels had the following percentage composition: protein 11.6, ether extract 67.0, N-free extract plus fibre 19.3 and ash 2.1.

Light petroleum, carbon disulphide and benzene are the best solvents for fat extraction. For hydraulic extraction the temperature should be maintained between 70° and 90° C. for seeds containing from 7 to 8 per cent. moisture.

The crude fat contained fatty acids 88.0, resins (?) 4.4, unsaponifiable matter 2.5 and glycerol radicals 5.1 per cent. Capric, lauric, myristic, palmitic, stearic, oleic and linoleic acid were identified in the fat, the value of which lies in its content of trimyristin and myristic acid: the latter comprised 61.3 per cent. of the total fatty acids.

P. C. Jowsey.

1672

PEREIRA PINTO, G. O óleo de patauá. [**Patauá oil.**] *Bol. téc. Inst. Agronom. Norte*, 1951, No. 23, 65–77. [Secç. Quím., Inst. Agronom. Norte, Brazil.] English summary.

Palmitic, stearic, oleic, linoleic and probably myristic acids were identified in the oil from *Jessenia bataua*. Oleic acid comprised 77.5 per cent. of the total fatty acids.

Physicochemical constants of the palm oil are listed. It closely resembles olive oil and may be used for similar purposes.—P. C. Jowsey.

CHIAO, J. S. and PETERSON, W. H. **Yeasts. Methionine and cystine contents.** *J. Agric. Food Chem.*, 1953, **1**, 1005–1008. [Dept. Biochem., Univ. Wisconsin, Madison.]

The optimum conditions for the liberation of methionine from yeast were hydrolysis for 1 hr. with 7 N HCl, from 1 to 2 hr. with 5 N HCl or 3 hr. with 3 N HCl, at 120° C. in an autoclave.

Seven commercial yeasts contained from 0.48 to 0.75 cent. methionine and 0.21 to 0.45 per cent. cystine on a dry matter basis.

Twenty species and strains of yeast were grown on Hawaiian molasses medium. Yields on the basis of sugars fermented ranged from 50 to 83 per cent. Methionine content ranged from 0.17 to 1.0 per cent. and cystine content from 0.19 to 0.58 per cent. on a dry matter basis.

The methionine content of *Saccharomyces cerevisiae* F-35 was not affected by addition of cystine,

12

threonine or choline to the medium, but 14.2 mg. cystine per 50 ml. medium increased the yield from 35.8 to 46.3 per cent. on the basis of sugars fermented.

Ammonium salts increased the yield and protein content of the yeasts, but had no effect on the methionine content.—P. C. Jowsey.

1676

SCHIELER, L., MCCLURE, L. E. and DUNN, M. S. **The amino acid composition of *Chlorella*.** *Food Res.*, 1953, **18**, 377–380. [Chem. Lab., Univ. California, Los Angeles.]

Chlorella pyrenoidosa and *C. vulgaris* were cultured aseptically. The cells were harvested by centrifuging, extracted first with acetone and then with ether and finally twice with cold and once with hot trichloroacetic acid, and dried. Seventeen amino-acids were estimated in the protein hydrolysates. The results indicated that *Chlorella* protein could serve as a source of amino-acids in animal feeding if supplemented with cystine, methionine and histidine.—W. Godden.

WYLAM, C. B. **Analytical studies on the carbohydrates of grasses and clovers. 3. Carbohydrate breakdown during wilting and ensilage.** *J. Sci. Food Agric.*, 1953, **4**, 527–531. [Dept. Chem., Univ. Edinburgh.]

With the methods previously described (Abst. 27, Vol. 22) it was found that when grass was allowed to wilt in the open there was considerable breakdown of sucrose and fructosan. If the grass was kept in a close-stoppered bottle the breakdown was more rapid and more extensive. The decrease in fructosan was not accompanied by a corresponding rise in fructose. When fresh grass was inoculated with a culture of mixed strains of lactobacilli and incubated under anaerobic conditions at 30° C. in the laboratory, there was almost complete disappearance of sucrose and fructosan and a considerable rise in fructose with the appearance of a small amount of galactose. The rise in fructose was much greater by the end of 8 months. The advantages of allowing grass to wilt before ensiling are discussed.—W. Godden.

1678

MOON, F. E. **Improving the nutritive value of Lothians' seeds-hay.** *Scot. Agric.*, 1953, **33**, 101–105. [Edinburgh and E. Scotland Coll. Agric.]

Lothian seeds hay is lower in protein than is generally reported for other areas. The average content, from analyses made between 1948 and

1951, was 5.98 per cent. of dry matter, with a digestibility of 35.8 per cent. The protein content can be increased by early cutting, or by increasing the amount of clover in the mixture. The former method means decreased yield and more difficulty in drying; attempts at the latter do not always meet with success. Another method is to apply a top-dressing of N fertiliser 2 or 3 weeks before cutting. Response to treatment depends on the intensity of the fertilising, the time interval between application and cutting and the rainfall after application. Average protein percentage in 4 years' tests on treated plots was 7.28; the digestibility of the protein also rose to 47.9 per cent. and the digestible protein was increased by 54 per cent. Since the other nutrients were not affected, the nutritive ratio was also improved, and the hay was suitable for maintenance of cattle without the use of a great deal of protein concentrate. The treatment also increased the yield of aftermath, though its protein percentage was below that of control plots. Recovery of the N applied was 40 per cent. in the first cut and a further 5 per cent. in the aftermath.—T. D. Bell.

1679

BOYLE, C. and RYAN, J. J. **The effect of late applications of nitrogen on the composition and yield of grass.** *J. Dept. Agric., Éire*, 1951–52, **48**, 44–48. [Univ. Coll., Cork.]

Duplicate plots of permanent pasture, each 1/100 acre in area, received the following treatments: nil (control), 1 or 2 cwt. per acre sulphate of ammonia, 4 or 8 tons per acre liquid manure containing about 0.14 per cent. N (8 tons approximately equalled 1 cwt. sulphate of ammonia). The trials were yearly for 6 years.

Average yields of dry matter were, in the above order, 51.0, 50.9, 51.2, 54.1, 54.6 cwt. per acre and the dry matter contained crude protein 9.40, 10.80, 12.32, 9.90, 10.32 per cent. The average yields of crude protein were 4.80, 5.50, 6.31, 5.35, 5.63 cwt. per acre.

It was concluded that late applications of N gave profitable results.—P. C. Jowsey.

SEARS, P. D. **Pasture growth and soil fertility. 1. The influence of red and white clovers, superphosphate, lime, and sheep grazing, on pasture yields and botanical composition.**

MELVILLE, J. and SEARS, P. D. **2. The influence of red and white clovers, superphosphate, lime, and dung and urine on the chemical composition of pasture.**

SEARS, P. D. and EVANS, L. T. **3. The influence of red and white clovers, superphosphate, lime, and dung and urine on soil composition, and on earthworm and grass-grub populations.**

N.A. and R., April 1954

SEARS, P. D. 4. The influence on soil fertility of clovers, superphosphate, lime, dung and urine applied to the pastures, as measured by the growth of subsequent forage crops. 5. The effects of nitrogenous fertilisers, and of "day" and "night" grazing. *N.Z. J. Sci. Technol. [A]*, 1953, **35**, Suppl. 1, 1-29; 30-41; 42-52; 53-67; 68-77. [Grasslands Div., D.S.I.R., Palmerston North.]

1. The effects of clovers, superphosphate, grazing, and dung and urine, singly and combined, on the yield and botanical composition of a mixed grasses pasture were studied over 5 years. The results are presented in detail.

No new principle of general applicability emerged but the results emphasised the complexity of the factors involved in the term "pasture production".

2. In this paper detailed data are given on the N, Ca, K and P contents of the herbage produced under the treatments described in Part 1.

3. Organic matter, N, P and exchangeable Ca, Mg and K were estimated in top soil from the plots used in the above tests. Estimates were also made of the earthworm and grass-grub (*Odontria* spp.) populations. The results are given in detail.

4. Data are presented for the yields and composition of rape, maize and Italian ryegrass crops grown subsequent to the pasture treatments described in Part 1. The total growth and the nutrients removed in the first rape and maize crops after the pasture were closely related to the previous pasture yields.

The results demonstrated the necessity of building up the fertility of pastures before taking a subsequent crop.

5. The yields and botanical composition of a ryegrass white clover pasture under different conditions of grazing and N fertilisation were studied.

N fertilisers had no marked effect on the total or seasonal yields and increased the grass: clover ratio only slightly.

Separate "day" and "night" grazing by sheep had a pronounced effect. Night grazing, from 4.30 p.m. to 8 a.m., induced extra growth, mainly of grass; day grazing caused a rise in the proportion of clover and a fall of total production. Subsequent rape crops grew better on the "night-grazed" plots.

The results are given in detail.—P. C. Jowsey.

1681

NATH, N. and DAS, N. B. Effect of growth stage on the chemical composition of some indigenous grasses of India. *Indian J. Vet. Sci.*, 1953, **23**, 43-51. [Indian Agric. Res. Inst., New Delhi.]

The grasses *Amphilophis odorata*, *A. glabra* and *Isilema laxum* were sampled at the young, pre-

flowering, flowering and ripe stages of growth and chemical analyses were made.

In all the grasses protein, ether extract, soluble ash, P_2O_5 , Na, K and Cl decreased and fibre increased with increasing maturity. N-free extract varied irregularly but tended to decrease. *I. laxum* had the highest average contents of protein, ether extract and minerals and also retained a high nutrient content longer than the others. The *Amphilophis* spp. had the most favourable Ca:P ratio in the young stage of growth and *I. laxum* in the flowering stage.—P. C. Jowsey.

1682

SHEPHERD, J. B., GORDON, C. H., WISEMAN, H. G., MELIN, C. G., CAMPBELL, L. E. and ROANE, G. D. Comparisons of silages stored in gas-tight silos and in conventional silos. *J. Dairy Sci.*, 1953, **36**, 1190-1200. [Bur. Dairy Indust., U.S. Dept. Agric., Washington, D.C.]

Dry matter, protein, ether extract, N-free extract, ash, sugar, carotene and pH were estimated in alfalfa-grass and soya bean silages stored in gas-tight and conventional silos. Feeding experiments with cows were made with some of the silages. The results are given in detail.

Silages stored in gas-tight and conventional tower silos were similar in composition, palatability, aroma, quality and feeding value. More dry matter, nutrients and carotene were preserved in the gas-tight silos, mainly because there was little or no top or side spoilage. Below the top silage in the tower silos, dry matter and nutrient losses were about the same as those in the gas-tight silos.

Air must be rigidly excluded from gas-tight silos during closed storage and, as far as practicable, when the silage is being used.—P. C. Jowsey.

1683

PERKINS, A. E., PRATT, A. D. and ROGERS, C. F. Silage densities and losses as found in laboratory silos. *Ohio Agric. Exp. Stat. Res. Circular* No. 18, April 1953, pp. 16. [Wooster, Ohio.]

A laboratory silo of about 9 lb. capacity is described and illustrated.

Silos of this type were filled with chopped maize sampled at different stages of growth or with chopped meadow herbage consisting typically of a mixture of clover, alfalfa, grasses and cereals. The average dry matter (DM) contents of the maize and meadow herbage samples ranged from 16.1 to 38.8 and 17.1 to 33.4 per cent., respectively. The contents of the silos were subjected to pressures ranging from 2 to 16 lb. per sq. in.

The results are presented in detail. A typical 9-lb. maize sample with a DM content of between 23 and 27 per cent. ensiled under pressures of 4, 6, 8, 12 and 16 lb. per sq. in. lost 0.147, 0.570, 0.613, 1.254 and 1.500 lb. by seepage.

Tables are presented relating the applied pressure and stage of growth to the density and weight of DM per c. ft. of silage. A maize crop with a DM content of 25.8 per cent., ensiled under a pressure of 2 to 4 lb. per sq. in. produced a silage which weighed, when moist, 49.0 lb. per c. ft. and which contained 12.67 lb. DM per c. ft. The same crop ensiled under a pressure of 14 to 16 lb. per sq. in. produced silage with a moist weight of 56.2 lb. per c. ft. and containing 14.48 lb. DM per c. ft.

It was concluded that the DM content of a crop should exceed 30 per cent. to avoid seepage. Juice lost by seepage from an immature crop may carry with it up to 10 per cent. of the DM originally ensiled. The results also indicated that dry materials do not pack well even if finely chopped and power and money can be saved by a coarser chopping to fill the lower 2/3 of the silo. The upper 1/3 only should be filled with moist, finely cut material.

In all silages the DM per c. ft. of settled silage varied less than the weight per c. ft. of moist silage and it is suggested that calculations of rations should be based on the former figure.

Finely cut material with a high moisture content packed too tightly and produced a cold silage with a high loss by seepage. Losses caused by escaping gases were less than 2 per cent.—P. C. Jowsey.

- SAHA, K. C., SEN, D. P. and MUKHERJEE, P. C. Investigations on fish-pond manures: 1. Studies on the nutritional values of some manure materials used for fertilizing fish-pond. *Ann. Biochem. Exp. Med.*, 1951, **11**, 203-206. [Technol. Lab., Directorate Fish., Govt. W. Bengal.]

Moisture, N, protein, Ca, P and K were estimated in 10 materials used as fish-pond fertilisers in India.

Fishmeal contained 7 per cent. N and was the richest source of this element, followed by mustard-seed cake and water hyacinth (*Eichhornia crassipes*) plants with 4.76 and 4.0 per cent. N, respectively.

Crabmeal contained most Ca, 12.3 per cent., followed by Jhowjhanji (*Hydrilla verticillata*), fishmeal and Kantajhanji (*Utricularia stellata*), containing 4.8, 3.0 and 2.6 per cent., respectively. Kantajhanji was rich in P, 3.0 per cent. Banana bark and arum stem had the most K, 5.1 and 4.9 per cent., respectively.

Fishmeal, crabmeal and mustardseed cake are expensive and studies are being made with a view to devising a fertiliser composed of the less costly materials.—P. C. Jowsey.

SQUIBB, R. L., GUZMÁN, M. and SCRIMSHAW, N. S. **Effect of pasture, dehydrated ramie meal, and sex on five blood serum constituents of New Hampshire chickens in Guatemala.** *Poultry Sci.*, 1953, **32**, 953-957. [Inst. Agropecuario Nac., Guatemala.]

New Hampshire pullets received a basal laying mash of ground sorghum and a protein concentrate,

or this mash supplemented with green kikuyu grass (*Pennisetum clandestinum*) or a dehydrated ramie (*Boehmeria nivea*) meal. Blood samples were taken at intervals of 3 weeks for 168 days. Pullets receiving the supplements had consistently higher amounts of total carotenoids and vitamin A in the blood serum than had birds on the basal ration alone. Serum riboflavin was highest in birds receiving kikuyu grass. Serum protein and ascorbic acid were similar in all groups. Sex differences in blood constituents were studied at 6, 12, 48 and 72 weeks of age, but no difference in total carotenoids, vitamin A, total proteins or ascorbic acid was found. The serum riboflavin was significantly higher in the females than in the males. In pullets aged 48 and 72 weeks riboflavin was higher than in pullets 6 and 12 weeks old, but in cockerels riboflavin did not vary with age.

E. M. Cruickshank.

1695

SHULTZ, F. T., GRAU, C. R. and ZWEIGART, P. A. **Vitamin supplements and squab production.** *Poultry Sci.*, 1953, **32**, 762-768. [Dept. Poultry Husb., Univ. California, Berkeley.]

Commercial pigeons of 3 strains received a basal ration of sweet corn, kaffir corn and milo, green peas, wheat and minerals, supplemented with vitamins A and D, riboflavin or vitamin B₁₂. The birds receiving riboflavin produced significantly more squabs than birds on the basal diet alone, which was due mainly to an increase of 10 per cent. in the hatching capacity of the eggs, and to a less extent to increased viability of the squabs. In birds receiving vitamin B₁₂ the increase in hatching capacity was 3 per cent., but it was not statistically significant, and the viability of the squabs was not improved. Addition of vitamins A and D was without effect, probably because the diet contained green peas and the squabs had access to sunlight. The supplements had no constant effect on the weight of the squabs.

E. M. Cruickshank.

VITAMIN A

1696

FLESCH, P. **A colorimetric method for determination of vitamin A and carotene by perchloric acid.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 148-149. [Dept. Dermatol., Sch. Med., Univ. Pennsylvania, Philadelphia.]

To 0.1 ml. of a chloroform solution containing vitamin A and carotene was added 1.6 ml. amyl acetate followed by 0.4 ml. concentrated HCl.

After the mixture had stood for 5 min. at room temperature, 2 ml. of a perchloric acid reagent, prepared by adding 1 part distilled water to 3 parts of a concentrated solution of perchloric acid, were added, followed by 0.4 ml. absolute alcohol. The mixture was shaken vigorously until the layers were mixed. Carotene gave a bluish-green colour with a broad maximum of absorption between 725 and 760 mμ. With vitamin A a blue colour

developed immediately, and almost instantly changed to purplish-red with maximum absorption between 520 and 530 $m\mu$. This colour remained for from 25 to 30 min., after which it turned yellow. Carotene was estimated directly by measuring the absorption at 750 $m\mu$, and vitamin A was calculated by subtracting from the absorption at 525 $m\mu$ the absorption value which corresponded to carotene at this wavelength. The colour developed with perchloric acid followed Beer's law over wider ranges than the colours obtained with previous methods, but the sensitivity was somewhat less.—R. J. Ward.

1697

McCOORD, A. B. **Use of 1, 2-dichloroethane in the Carr-Price antimony trichloride reagent for the determination of vitamin A.** *J. Lab. Clin. Med.*, 1953, **42**, 660-662. [Dept. Paediat., Sch. Med., Univ. Rochester, N.Y.]

Chloroform, normally used as the solvent for antimony trichloride in the preparation of the reagent for estimating vitamin A, has the disadvantage that it decomposes after one or two months' storage. In place of chloroform 1:2-dichloroethane may be used, and the solutions were found not to deteriorate on standing. It was found also that commercial specimens do not require to be purified. Solution of 30 g. $SbCl_3$ in 100 ml. dichloroethane gave the best results; more dilute solutions gave blue colours which were more transient. As with chloroform, precautions are necessary with dichloroethane, and prolonged breathing of its vapour must be avoided. An Evelyn photo-electric colorimeter with filter 620 was used to estimate vitamin A, but the reagent could be used with other colorimeters. When a given amount of vitamin A was treated with the dichloroethane $SbCl_3$ reagent and with the usual chloroform $SbCl_3$ reagent the intensity of the resulting blue colour was the same.

1698

MITCHELL, H. L. and SILKER, R. E. **Carotene. Determination in alfalfa meal treated with N, N'-diphenyl-p-phenylenediamine.** *J. Agric. Food Chem.*, 1953, **1**, 1163-1165. [Kansas Agric. Exp. Stat., Manhattan.]

The A.O.A.C. method of analysis has been found to give falsely high values for the carotene content of alfalfa meals that have been treated with Dpppd (N,N'-diphenyl-p-phenylenediamine) (Abst. 4123, Vol. 23). It was, therefore, modified by evaporation of the extract to remove acetone, addition of light petroleum, chromatography on tricalcium phosphate instead of magnesia, and measurement of the extinction of the eluate at 436 $m\mu$. A filter aid was mixed with some brands of tricalcium phosphate to hasten percolation. When meals

were analysed by both the modified and the unmodified A.O.A.C. method the former gave slightly lower values for carotene. The reasons are discussed. Meals were treated separately with up to 0.2 per cent. of Dpppd and 6-ethoxy-2:2:4-trimethyl-1:2-dihydroquinoline as anti-oxidants. The latter increased the apparent value for carotene by 5 per cent. with the A.O.A.C. method, and not at all with the phosphate method. The addition of Dpppd increased the apparent carotene value by 5 per cent. with the phosphate method and to a much greater extent with the A.O.A.C. method. The phosphate method is therefore recommended as satisfactory for estimating carotene in alfalfa meals that have been treated with Dpppd.—V. H. Booth.

1701

WALD, G., BROWN, P. K. and SMITH, P. H. **Cyanopsin, a new pigment of cone vision.** *Science*, 1953, **118**, 505-508. [Biol. Labs., Harvard Univ., Cambridge, Mass.]

Three visual pigments have been known heretofore. Retinene₁ combines with rod opsin to make rhodopsin, or with cone opsin to make iodopsin. Retinene₂ combines with rod opsin to make porphyropsin. Preparation of the fourth possible combination, retinene₂ with cone opsin, is here described. The substance obtained was a blue, light-sensitive pigment with an absorption maximum at 620 $m\mu$. The name cyanopsin is proposed for it.—E. M. Hume.

1702

DEUEL, H. J. (Jr.) and GREENBERG, S. M. **A comparison of the retention of vitamin A in margarines and in butters based upon bioassays.** *Food Res.*, 1953, **18**, 497-503. [Dept. Biochem., Univ. S. California, Los Angeles.]

N.A. and R., April 1954

Vitamin A in 8 brands of margarine and 4 samples of butter was estimated biologically. Cod liver oil was first used as standard, but was later replaced by vitamin A acetate. Two of the margarines contained vitamin A alcohol, 4 a distilled ester and 2 a natural ester. The original vitamin A content of the margarines ranged from 34.2 to 53.0 U.S.P.U. per g. and of the butter from 37.5 to 67.0. After 2 years at 14° F. the average retention of vitamin A was 83 per cent. for the margarine and 78 per cent. for the butter. The average percentage retentions were, respectively, after from 52 to 60 weeks at 41° F. 80 and 84, after 45 weeks at 64° F. 53 and less than 45, and after 41 weeks at 82° F. 35 and 34.—R. J. Ward.

1703

MELNICK, D., LUCKMANN, F. H. and VAHLTEICH, H. W. **The retention of preformed vitamin A and carotene in margarine based upon physico-chemical assays.** *Food Res.*, 1953, **18**, 504-510. [Res. Labs., The Best Foods, Inc., Bayonne, N.J.]

Samples of coloured and uncoloured margarine produced at 3 different plants over 18 months were tested for carotene and vitamin A by a spectrophotometric method, when fresh and after 3 months at 45° F. The average vitamin A content of the fresh uncoloured margarine from the 3 plants was 17,200, 16,900 and 17,250 U.S.P.U. per lb. After 3 months at 45° F. the average percentage retention of vitamin A was 99.7, 98.2 and 98.5, respectively. For the coloured margarine the vitamin A content of the fresh samples was 11,900, 11,100 and 11,100 U.S.P.U. per lb., with respective percentage retentions of 99.7, 98.0 and 98.5 after 3 months at 45° F. The average carotene content of the fresh coloured margarine was 5700, 6700 and 6750 U.S.P.U. per lb. with respective percentage retentions of 96, 97.1 and 96.3 after 3 months at 45° F.

When the margarines were held at 75° F. for 1 month, the average percentage retention for the uncoloured samples from the 3 plants was 91.8 by the spectrophotometric method and 96.3 by the SbCl_3 method. For the coloured margarine the corresponding values were 91.6 and 98.0. The difference in results of the two methods was attributed to the presence of anhydrovitamin A in the margarine. The average retention of carotene was 93.6 per cent.—R. J. Ward.

MURRAY, T. K. and CAMPBELL, J. A. **A note on the stability of vitamin A in Canadian margarine.** *Canad. J. Technol.*, 1953, **31**, 193-195. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa.]

Vol. 24, No. 2

Samples of margarine from 13 manufacturers were stored at room temperature and at 5° C. for 12 months. Vitamin A was estimated by the SbCl_3 method after 3, 6, 9 and 12 months at room temperature and after 12 months at 5° C. The peroxide number was determined on the material when fresh and after 12 months' storage at room temperature and at 5° C. The average vitamin A content of 12 of the brands which satisfied the label claim was 4000 I.U. per 100 g. After 12 months' storage, 10 of the products still met or surpassed the label claim with an average vitamin A content of 3720 I.U. per g., which represented a loss of 10 per cent. With the refrigerated samples the loss was 1.7 per cent., with the same 10 brands equalling or surpassing the label claim. Results of peroxide estimations showed that there was a positive correlation between vitamin A loss and peroxide number.—R. J. Ward.

KARMAKAR, G., NEOGI, S. and RAJAGOPAL, K. **The stability of carotene concentrate from water-hyacinth dissolved in vegetable oils.** *Ann. Biochem. Exp. Med.*, 1952, **12**, 1-16. [Dept. Biochem. Nutrit., All-India Inst. Hyg., Calcutta.]

A carotene concentrate was prepared from leaves of the water hyacinth. Portions were dissolved in arachis oil and in mustard oil, and the carotene was estimated at intervals. The loss of carotene was much greater at high than at low temperatures and the percentage loss was greatest with lowest initial concentration. Wheat germ oil, *dl*-methionine and α -tocopherol were added to solutions in oil, separately or together. Presence of 0.01 per cent. α -tocopherol reduced the percentage loss of carotene from mustard oil in 12 hr. at 100° C. from 48 to 28. The other anti-oxidants had less effect. Carotene in either of the oils was quickly destroyed by ultraviolet light.

WALSH, K. A. and HAUGE, S. M. **Carotene. Factors affecting destruction in alfalfa.** *J. Agric. Food Chem.*, 1953, **1**, 1001-1004. [Dept. Biochem., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Samples of alfalfa, autoclaved, blanched or untreated, were frozen and then ground in ice water. Portions of the paste were suspended in water or buffer solution and incubated over lamps or in the dark. Carotene was then extracted and the loss estimated.

There seemed to be three mechanisms of destruction. Loss from autoclaved alfalfa, incubated in light, was called photochemical loss; loss from autoclaved alfalfa, incubated in darkness, was assumed to be due to auto-oxidation. Loss from untreated alfalfa, incubated in light, represented the total loss from all mechanisms. The auto-oxidative loss was small and was included in each of the others. It was difficult to assess the relative importance of the three mechanisms under field conditions because inhibition of one system seemed to permit another to proceed faster.

The enzyme system had an optimum pH between 4 and 5 and an optimum temperature of about 43° C. The photochemical system was not sensitive to pH or much affected by temperature. Prolonged blanching or autoclaving had little effect on the photochemical loss, and cyanide had none. A large amount of cyanide was needed to inhibit the enzyme system and inhibition was only partial. Unless the system was well buffered, cyanide reduced the activity of the enzyme also by raising the pH, which may explain why earlier workers found complete inhibition with cyanide.

HERB, S. F., RIEMENSCHNEIDER, R. W., KAUNITZ, H. and SLANETZ, C. A. **Nature of the "vitamin A-like factor" in lard.** *J. Nutrition*, 1953, **51**, 393-402. [E. Reg. Res. Lab., Philadelphia, Pa.]

A fraction from the molecular distillation of lard had a biological activity of 4.5 "units" vitamin A per g., and was subjected to further molecular distillation. About 15 per cent. was removed as 4 fractions. Another portion was crystallised from acetone, a precipitate was removed at 0° C.

and another at -45° C. Biological tests were made on all the fractions. Molecular distillation yielded the fractions with the highest activity, and when the unsaponifiable residues of these fractions were examined spectrophotometrically, an inflection in the spectral curve was obtained at about 325 mμ. A further quantity of the distillate was redistilled in the same way except that about 2.5 per cent. was removed as a first fraction and 7.5 per cent. as a second fraction. Chromatographic fractionation of the unsaponifiable residues of these two fractions, and subsequent spectrophotometric examination of the eluted fractions, gave only qualitative indications of the presence of vitamin A because of too great absorption in the region from 300 to 320 mμ. The undistilled fraction, which had little unsaponifiable matter, was saponified and fractionated chromatographically. Eluted fractions which gave the Carr Price reaction were combined and examined spectrophotometrically. The curves obtained showed a slight maximum at 325 mμ. and another at 310 mμ. When a correction had been made for irrelevant absorption the distillate was calculated to have a potency of 1.7 "unit" per g. A further fraction from the original lard distillation had a biological value of 25 "units" per g.; it was subjected to the treatment described above and a spectral absorption curve typical of vitamin A was obtained. After correction for irrelevant absorption, a calculated value of 23.9 "units" per g. was obtained. When a sample of fresh lard was saponified and fractionated chromatographically, eluates were obtained which gave a spectral curve resembling that of vitamin A except for slight extraneous absorption in the region from 300 to 320 mμ. The potency calculated from the spectral curve after correction was 0.4 "unit" per g. lard.

LOWE, J. S. and MORTON, R. A. **Studies in vitamin A. 26. The vitamin A-replacing effect of lard.** *Biochem. J.*, 1953, **55**, 681-686. [Dept. Biochem., Univ. Liverpool.]

Chromatography of lard and its unsaponifiable matter failed to yield a fraction which would give a positive test for vitamin A or carotene by spectrophotometric examination in the ultraviolet or by the SbCl₃ test. A fraction obtained by molecular distillation of lard at from 210° to 220° C. was supplied in an amount of 0.6 g. daily in the diet of rats which had been depleted of vitamin A till they ceased to grow and had signs of xerophthalmia. Other depleted rats were given a diet containing arachis oil and a supplement of 6 I.U. vitamin A daily. Both groups grew rapidly and the eye lesions were completely cured. Analysis of the blood plasma, liver and kidneys failed to show the presence of vitamin A in the rats

N.A. and R., April 1954

given lard distillate; the other rats had 52.3 I.U. per ml. in the plasma and 7 I.U. per g. in the kidney, but none in the liver. The average weight gain in 23 days was 41 g. for those given vitamin A and 39 g. for those given lard distillate.

LOWE, J. S., MORTON, R. A. and HARRISON, R. G. **Aspects of vitamin A deficiency in rats.** *Nature*, 1953, **172**, 716-719. [Dept. Biochem., Univ. Liverpool.]

The presence of traces of vitamin A and carotene in "light white casein", and the ability of light white casein to support slow growth in rats otherwise deficient in vitamin A, have been confirmed. Further evidence has been obtained that no vitamin A can be detected in the livers and other organs of rats subsisting on such low intakes, but normal amounts of rhodopsin were found in the retina. In confirmation of the claim of Kaunitz and Slanetz (Abst. 4883, Vol. 20), a distillate from lard was found to have slight biological activity, but no vitamin A or carotene could be detected by chemical methods. In spectroscopic studies of the unsaponifiable matter of the livers of rats deprived of vitamin A, a fraction was separated with absorption maxima at 275 and 332 $m\mu$. and with inflections at 233 and 283 $m\mu$. Similar absorption was seen in an extract of the tissues surrounding the eyes of rats with xerophthalmia. From the liver of an old, worn-out horse a fraction absorbing at 270 $m\mu$. was separated, and 3:5-cholestadiene-7-one was detected. From the spectroscopic studies it was inferred that vitamin A deficiency causes the appearance of abnormal metabolic products in the tissues, possibly by lifting the restraint on the dehydrogenation of cholesterol or steroid hormones. In histological studies of the adrenal glands of rats deprived of vitamin A, the distribution of lipids and cholesterol appeared to be normal, but phospholipins were reduced and confined to the *zona glomerulosa*.

ESH, G. C. and BHATTACHARYA, S. **Studies on the utilization of vitamin A. 3. Utilization of vitamin A palmitate.** *Indian J. Physiol. Allied Sci.*, 1953, **7**, 153-157. [Bengal Community Res. Inst., Calcutta.]

Weanling albino rats were depleted in vitamin A, and divided into groups of 6. Concentrates of vitamin A palmitate dispersed in arachis oil, ethyl oleate or an aqueous medium with Tween 20 or Tween 60 as dispersing agent were given to different groups of rats for 4 consecutive days at the rate of 720 I.U. vitamin A daily. The rats were rested on the fifth day and killed on the sixth when the livers were removed and vitamin A

was estimated in them. The percentage stored of the ingested vitamin A was 61.8 and 63.6 with the aqueous media, only 44.7 when the vitamin was given in arachis oil, and 34.7 when it was given in ethyl oleate. When the results were compared with those previously obtained (*Indian J. Physiol. Allied Sci.*, 1952, **6**, 43) for vitamin A acetate and vitamin A alcohol, the highest storage from all the media studied was found to be with vitamin A palmitate. When fortified with tocopherol as anti-oxidant, with lecithin or propyl gallate, significant increase in liver storage was obtained from arachis oil and ethyl oleate as solvents; thus, addition of tocopherol and lecithin together increased the percentage stored to 49.0 from 34.7 when ethyl oleate was used. No such increase occurred with the aqueous media. In a subsequent experiment smaller doses of from 10 to 34 I.U. vitamin A palmitate were given daily for 21 days and the solvent then had no significant influence on growth rate or liver storage and the results were almost identical with those for vitamin A acetate.—I. M. Sharman.

JAMES, W. H. and ELGINDI, I. M. **The utilization of carotene. 1. As affected by certain proteins in the diet of growing albino rats.** *J. Nutrition*, 1953, **51**, 97-108. [Dept. Agric. Chem., Louisiana Agric. Exp. Stat., Baton Rouge.]

Male weanling rats which had been depleted of vitamin A were given a diet with casein or lactalbumin or gluten or zein and casein. The diets were equivalent in energy and protein and approximately equivalent in P. Each rat was given a daily dose of 21 μ g. β -carotene and 1 mg. α -tocopherol. They were weighed weekly and the food intake was recorded. Blood was taken for vitamin A analysis by the micromethod of Bessey *et al.* (Abst. 4004, Vol. 16) 4 and 8 hr. after the initial dose of carotene, 8 hr. after the second dose, 16 hr. after the third dose, and 16 to 20 hr. after the dose of carotene every 3 days subsequently. All the faeces were collected from each rat and analysed for carotene. After 6 weeks the rats were killed, and vitamin A was estimated in the liver.

The final average bodyweight of the 4 groups was 207, 198, 167 and 126 g., respectively. The vitamin A content of the liver was 69, 35, 41 and 12 μ g., respectively. The carotene excretion was 191, 282, 254 and 162 μ g. and the amount of carotene unaccounted for was 632, 572, 595 and 714 μ g., respectively. The value for vitamin A in the blood of the rats that received casein or lactalbumin was about 17 per cent. higher in the first 30 days than that of those that received gluten or casein and zein. After the 30th day no significant difference was found.—R. J. Ward.

1714

CHOU, T. C. and MARLATT, A. L. **Some factors in the Chinese diet affecting carotene utilization.** *J. Nutrition*, 1953, **51**, 305-315. [Dept. Foods Nutrit., Sch. Home Econ., Kansas State Coll., Manhattan.]

Male weanling rats of the Sprague Dawley strain were fed on a diet deficient in vitamin A until growth ceased and eye lesions appeared. During the following 4 weeks, groups of 6 were given supplements of carotene and were weighed; they were then killed and vitamin A was estimated in the serum and liver.

The first experiment, designed to test the efficiency of soya bean, groundnut and sesame oils as carriers for crystalline carotene, showed respective utilisation values of 1.00, 0.69 and 1.84 for the 3 oils. The superiority of sesame oil was at variance with the relative amount of tocopherol that it supplied, 11.5 mg. per kg. diet, compared with 27.5 μ g. for soya bean oil. Addition of 1 per cent. lecithin or 0.1 per cent. ascorbic acid to the diet containing 5 per cent. soya bean oil produced no significant synergistic effect when the average intake of carotene was 91 μ g. daily.

A second experiment used typical Chinese foods as sources of carotene and of fat, lecithin and ascorbic acid. To supply carotene, part of the Irish potato normally present in the diet was replaced by carrot, sweet potato, or the green leafy vegetable *woo-chei-pei*. The values for the utilisation of carotene from these sources did not differ significantly, and were between 35 and 67 per cent. of the utilisation value for crystalline carotene given in the soya bean oil diet.

EVELETH, D. F., GOLDSBY, A. I., BOLIN, F. M. and BOLIN, D. W. **Effect of parasitism on conversion of carotene into vitamin A by sheep; a preliminary report.** *Vet. Med.*, 1953, **48**, 441-442. [Dept. Vet. Sci., N. Dakota Agric. Exp. Stat., Fargo.]

Two-year-old native grade sheep which had been kept from weaning on a ration low in carotene were used for the experiment. Of 4 animals, 1 was not infested with parasites; the others were given from 27,000 to 3,900,000 filariform larvae by stomach tube. After initial biopsy specimens had been taken each sheep was given, also by stomach tube, 60,000 "units" of carotene dispersed in water. After 16 hr. further biopsy specimens were taken from the non-infested and an infested sheep, and 2 hr. later from the remainder. All the sheep were slaughtered 40 hr. after they were given carotene.

The vitamin A content of the liver rose in the non-infested sheep from 5.1 to 14.4 I.U. per g.; the corresponding values for the infested sheep

were from 2.6 to 6.1, 2.7 to 1.6 and 3.4 to 6.2, showing that the non-infested sheep was more effective in converting the carotene supplied into vitamin A. There was, however, no correlation with the value for vitamin A in the serum.

HARPER, T. A., BOUCHER, R. V. and CALLENBACH, E. W. **Vitamin A and survival of bobwhite quail.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 567, June 1953, pp. 21. [State College, Pa.]

Experiments with 953 bobwhite quail, including 90 adults, are described. All chicks were fed on a basal diet low in vitamin A. In addition, all birds except those in a negative control group received a supplement of 3000 I.U. vitamin A per lb. diet. In the first experiment with pedigree chicks lasting for 16 weeks, the growth, mortality and storage of vitamin A were studied, and also the time of survival on a diet low in vitamin A and without food. Growth, liver weight and percentage mortality were about the same for 4 different strains, provided the supplement of vitamin A was given. In a second experiment 3 groups of chicks from parents selected as differing in ability to withstand a long winter period on the restricted diet were given an all-wheat depletion diet. Growth during a 16-week experimental period was about the same in the 3 groups. No significant difference in liver size or storage of vitamin A was found. Of 29 quail aged 16 weeks, none survived starvation for more than 89 hr. Of 88 birds, also aged 16 weeks, given the diet without vitamin A, 2 in a group of 33 survived 45 days and 2 in another group of 55 survived 37 days. In a third experiment the basal diet used in the first 2 experiments was confirmed as of low vitamin A content. One group of 100 quail were fed on the basal diet supplemented with 3000 I.U. vitamin A per lb. diet, and another group of 100 received the unsupplemented diet; of the latter 60 died from deficiency of vitamin A after 3 weeks and all died within 8 weeks.—I. M. Sharman.

MILLEN, J. W., WOOLLAM, D. H. M. and LAMMING, G. E. **Hydrocephalus associated with deficiency of vitamin A.** *Lancet*, 1953, **265**, 1234-1236. [Dept. Anat., Univ. Cambridge.]

Hydrocephalus was found to be the cause of nervous disorders in young rabbits, aged from 2 to 8 weeks, from 5 does that had been deprived of

N.A. and R., April 1954

vitamin A since 14 weeks before mating. It was caused by stenosis of the cerebral aqueduct. Paralysis and constriction of the optic nerve were secondary effects.—T. Moore.

1719

MEUNIER, P., ZWINGELSTEIN, G. and JOUANNEAU, J. Variations du taux des phénols urinaires au cours de la carence en vitamine A chez le rat. [Variation in the amount of phenols in the urine during vitamin A deficiency in the rat.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1189-1191. [Lab. Chim. Biol., Fac. Sci., Lyons.]

Male albino rats were kept on a diet deficient in vitamin A until their growth had stopped. Others were given 2.5 μ g. vitamin A daily. Estimation of total phenols in the urine tended to give higher values for the deficient animals than for the non-deficient. In rats given vitamin A or deprived of it, administration of 1 mg. ascorbic acid daily tended to reduce the excretion of phenols.

LUDWIG, K. S. Vitamin A-Mangel und Überdosierung und ihre Beziehungen zum Gehalt an alkalischer Phosphatase der Epiphysenfuge. [Vitamin A deficiency and excess and their relations to the alkaline phosphatase content of epiphyseal cartilage.] *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 98-103. [Anat. Inst., Univ. Basle.] French and English summaries.

Weanling rats were kept for 6 weeks on a diet deficient in vitamin A, which was supplemented for some of them with adequate doses of the vitamin. Others were given, when two months old, the same diet with or without daily doses of 100,000 I.U. vitamin A for from 7 to 10 days. Deficiency of vitamin A was shown in the first group by cessation of growth, and vitamin A excess in the later groups by skeletal fractures. Sections of the bones were stained for alkaline phosphatase. In the distal epiphysis of the femur, the amount of phosphatase was decreased in deficiency and increased in excess. Much less intense phosphatase staining was found in the proximal epiphysis of the tibia after all treatments. Staining was most intense in the bones which had been fractured.—T. Moore.

BRUSA, A. and TESTA, F. Lesioni nel sistema nervoso centrale di cavie in ipervitaminosi A. [Lesions of the central nervous system in guineapigs given excess of vitamin A.] *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 55-62. [Ist. Clin. Pediat., Univ. Genoa.] German, French and English summaries.

Vol. 24, No. 2

Guineapigs weighing from 350 to 600 g., fed on a normal diet, were given a daily oral dose of from 300 to 600 I.U. vitamin A per g. bodyweight. They died in from 10 to 16 days. Portions of the central nervous system were fixed in formalin. Histological examination showed severe lesions in the cerebral cortex, cerebellum, thalamus and mesencephalon.—E. M. Hume.

1722

MADDOCK, C. L., COHEN, J. and WOLBACH, S. B. Effect of hypervitaminosis A on the testes of the rat. *Arch. Pathol.*, 1953, **56**, 333-340. [Div. Nutrit. Res., Child. Hosp., Boston, Mass.]

Male weanling rats were given a synthetic diet and, daily for 6 weeks or until they died, 250 I.U. vitamin A as palmitate per g. bodyweight. At autopsy degenerative changes were found in the testes; the spermatozoa were reduced in numbers, and chromatin was lost from the spermatids and spermatocytes. Later, sloughing of the spermatocytes and clumping of their nuclei and of those of the spermatids caused the formation of giant cells. Finally the germinal epithelium was almost completely sloughed away. The changes were thought to be non-specific and to resemble those produced by inanition.

The addition of α -tocopheryl acetate in massive doses of 10 or 100 mg. per 50 g. bodyweight intensified the injuries caused by vitamin A. The testes were severely injured also in rats given only vitamin A in conjunction with a stock diet. When the dose of vitamin A was reduced to 100 I.U. per g. bodyweight and was given for up to 100 days in conjunction with a synthetic diet, with or without tocopherol, the injuries to the testes were moderately severe. Only trifling changes occurred in the testes of rats which were allowed to become sexually mature before being given, for up to 7 weeks, 100 I.U. vitamin A per g. bodyweight, with a synthetic diet and with or without vitamin E. Haemorrhage, which was a common cause of death before the end of the intended period of treatment with vitamin A, occurred more often in rats given the synthetic diet than in those given the stock diet. The tendency to haemorrhage was intensified by tocopherol.—T. Moore.

SIMIC, B. S., SINCLAIR, H. M. and LLOYD, B. B. The activity of ascorbic acid in hypervitaminosis-A in the guinea-pig. *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 7-20. [Lab. Human Nutrit., Univ. Oxford.] German and French summaries.

Young male guineapigs were fed on a pelleted diet deficient in vitamins A and C. The first group of 9 received an adequate daily intake of 20 mg.

ascorbic acid, and of 100 I.U. vitamin A. A second group of 11 received the same amount of ascorbic acid but excess of vitamin A, 40,000 I.U. The third group, also of 11, received the same excess of vitamin A and 500 mg. ascorbic acid. L-Tyrosine was given to the animals on certain days. On the 34th day all surviving animals were bled from the jugular vein for estimation of plasma ascorbic acid, and on the 41st day they were killed for estimation of ascorbic acid, tyrosine, vitamin A, protein and Hb in the blood and of ascorbic acid, tyrosine and vitamin A in the liver.

Average values for vitamin A in the liver of the three groups were 130, 8280 and 7500 I.U. per g., and for vitamin C in the plasma they were 0.310, 0.520 and 0.899 mg. per 100 ml., respectively. Both values were negatively correlated with the average value for tyrosyl in the liver, 76, 67 and 38 mg. tyrosine per 100 g. Excess of vitamin A appeared to interfere with general liver function and so to depress the catabolism of tyrosine in the liver. Signs of vitamin A intoxication appeared in the last two groups, and there was no evidence of any preventive effect of a high intake of ascorbic acid.—I. M. Sharman.

ELLENBERGER, H. B., NEWLANDER, J. A. and JONES, C. H. **Effects of feeding different grades of hay and cod-liver oil concentrate to dairy cattle. 2. From 91 to 360 days of age.** *Vermont Agric. Exp. Stat. Bull.* No. 570, June 1953, pp. 88.

The trials were planned as tests of Ca and P requirements but were modified to show also whether calves given feeds ordinarily available are benefited by supplements of vitamins A and D. A previous report (Abst. 326, Vol. 22) covered the first 3 months of life; the present report covers the second, third and fourth 3-month periods. Intake, weight gain, blood analysis and several other sets of data for live and slaughtered animals are shown in tables, and comparisons are made with standard animals. The present Abstract is concerned only with the results relating to vitamins A and D.

The experiment, which lasted 12 years, was continued through 5 generations. A total of 61 heifer and 25 bull calves was divided into 4 groups, given good hay or poor hay with and without cod liver oil. The feed consisted of 3 parts each of maize meal, ground oats and wheat bran, and one part linseed meal with 1 per cent. salt. Each calf was allowed all it would eat of this mixture up to 4 lb. daily with chopped hay to appetite and grass clippings or silage when in season. The calves went outdoors for limited periods daily if weather permitted.

The average weight gain during the final 10-month period expressed as percentage of normal was for good hay 94, good hay and cod liver oil 99, poor hay 80, poor hay and cod liver oil 87, so that cod liver oil improved both hays, but good hay alone was better than poor hay with cod liver oil.—V. H. Booth.

PROTSEV, B. M. **Dinamika soderzhaniya karotina v kvashenoi i sushenoi morkovi. [Carotene content in fermented and dried carrots.]** *Gigiena Sanit.*, 1952, No. 10, 34-37.

Carrots were fermented by treating the pulped material with 4 to 5 per cent. solution of cooking salt, and the paste formed was kept at from 20° to 25° C. till foaming ceased. The fermented material was then stored at from 0° to 3° C. The carotene content decreased by from 30 to 32 per cent. on storing the fermented carrots for 11 months. Dried carrots contained per cent. from 10.5 to 16.5 mg. carotene, though about 65 per cent. of the carotene in the original sample was destroyed by the drying process. When the dried carrots were kept for 2½ months in the light but without access of air the amount of carotene decreased by from 10 to 11 per cent.; with access of light and air the decrease was from 16 to 19 per cent.—W. Hughes.

LEWIS, E. F. and BURROW, H. The effect of dihydrotachysterol on bovine blood calcium, inorganic phosphate and sugar levels. *Brit. Vet. J.*, 1953, **109**, 521-525. [Dept. Med., Royal Vet. Coll., Streatley.]

Intramuscular injection of dihydrotachysterol into 3 cows produced a consistent rise in the blood Ca value which was maintained for about 4 days. In one cow given the drug orally the response was similar but slower, and the effects were maintained for longer. The blood inorganic P value was depressed in all, but in 2 animals it eventually rose to a value higher than the initial one. The blood sugar value was generally raised, but the value for blood Mg appeared to be unaffected. It is suggested that dihydrotachysterol may prove of value in retarding the development of symptomatic hypocalcaemia, and in preventing the relapse of cases treated by ordinary methods, but the need for care is pointed out where the value for blood P is low. It is suggested also that the drug may prove useful for combating ketosis in normal pregnancy and parturition.—W. A. Greig.

1729

HANSSLER, H. Experimentelle Untersuchungen über die Beziehungen der Nebenschilddrüsen-morphologie und -Funktion zur Vitamin D-Wirkung. [Experimental studies on the relations between the morphology and function of the parathyroid glands and the action of vitamin D.] *Ztschr. ges. exp. Med.*, 1953, **121**, 209-227. [Kinderklin., Univ. Tübingen.]

A total of 124 rats from 4 to 5 weeks old, fed on a constant diet, were kept for 5 or 6 days in a dark room at 25° C. before being given parathyroid hormone or vitamin D for varying periods. They were killed fasting, and serum Ca and P were estimated, organs were fixed in formalin for histological examination, and statistically controlled measurements of the size of nuclei were made.

When 400 units of parathormone Lilly were given daily for 6 days, there was some increase of serum Ca and reduction of serum P, with diminution in size of the nuclei in the parathyroid gland. When vitamin D₂ or D₃, about 30 µg. daily mixed in the food, was given instead of parathormone for up to 13 days, the results were the same. Smaller doses, about 10 µg. daily, were effective also. An inverse relationship could be detected between the size of the parathyroid gland nuclei and the value for serum Ca. The state of the parathyroid gland in which the nuclei were small was taken to be one of rest, and histological examination of the thyroid

gland showed that its cells also entered into a state of rest in the same circumstances as the cells of the parathyroid gland.

The statistically controlled measurement of nuclei is recommended as a possible means of assessing the activity of glandular tissue.

GRANT, A. B. Carotene: a rachitogenic factor in green-feeds. *Nature*, 1953, **172**, 627. [Wallaceville Animal Res. Stat., Wellington, N.Z.]

When groups of 18 rats were given 0.075 or 0.15 I.U. vitamin D daily the average percentage ash in the dry, fat-free femur was 33.2 and 37.9, respectively. When the daily dose of 0.15 I.U. vitamin D was supplemented with 1.75, 3.5, 7.0, 14.0 or 28.0 mg. dried grass daily, which represented 1.2, 2.4, 4.8, 9.6 or 19.2 µg. carotene, the average percentage ash was 38.1, 36.3, 35.6, 32.9 and 31.6, respectively. When groups of 24 rats were given daily 0.05, 0.10 or 0.20 I.U. vitamin D only, the average percentage was 32.4, 34.3 and 38.7. When similar groups of rats were given 0.15 I.U. vitamin D and 0.781, 3.125, 12.5, 50.0 or 100.0 µg. carotene the average percentage ash was 34.9, 34.3, 32.6, 31.2 and 30.6, respectively. A daily dose of 50 I.U. vitamin A had a similar effect, and reduced the average percentage ash from 34.1 to 31.8.—R. J. Ward.

TAUGNER, R. and FLECKENSTEIN, A. Kapillarabdichtung durch Ultraviolettstrahlung und Vitamin D. Versuche an weissen Ratten bei ernährungsbedingter und toxischer Kapillarschädigung. [Increase in capillary strength caused by ultraviolet irradiation and vitamin D. Experiments with white rats on capillary injury caused by diet and toxins.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1952-53, **5**, 89-97. [Pharmakol. Inst., Univ. Heidelberg.] English and French summaries.

Male white rats weighing from 150 to 200 g., maintained on a diet of maize only, showed after from 3 to 5 weeks fragility of the capillaries which was demonstrated by a negative-pressure method on the skin of the abdomen. Exposure to sunlight for a short time, 15 min. in St. Moritz (1800 m.) or 60 min. in Heidelberg, restored the capillary resistance to normal for about 3 days. The same effect was obtained with an ultraviolet ray lamp or intravenous injection of 10 µg. vitamin D₂ or D₃ per 100 g. bodyweight.

Capillary fragility induced with puff-adder venom gave doubtful results on treatment with vitamin D or ultraviolet light.—E. M. Hume.

1732

BUBNOFF, M. v. and TAUGNER, R. Sonnenbestrahlung und Kapillarabdichtung. Vergleichende Untersuchungen über die Stärke der kapillarabdichtenden Wirkung des Sonnenlichtes in Heidelberg, St. Moritz und auf der Corviglia. [Solar irradiation and increase in capillary resistance. Comparative investigation of the capillary-strengthening activity of sunlight in Heidelberg, in St. Moritz and on the Corviglia.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1952-53, **5**, 272-278. [Pharmakol. Inst., Univ. Heidelberg.] French and English summaries.

Capillary resistance was measured as described (see preceding Abst.) with groups of from 8 to 12 rats before and after exposure to ultraviolet light or intravenous injection of vitamin D in water-soluble form. Tissue permeability was measured by the rate of disappearance of methylene blue or fluorescein injected into the shaved abdominal skin.

The same effect was produced by exposure with a clear sky to sunlight for 30 min. at Heidelberg (120 m.) or 15 min. at St. Moritz (1800 m.) or 5 min. on the Corviglia (2450 m.), or to a quartz mercury vapour lamp for 10 min. Somewhat weaker was the effect of injecting 10 μ g. vitamin D₂. A stay on the Corviglia without exposure to sun had no effect.

Absorption of fluorescein and methylene blue was retarded by the exposures but the results did not run quite parallel to those for capillary resistance.—E. M. Hume.

1733

KLUNGSÖYR, L. and PIHL, A. The alleged effect of vitamin D on skin respiration. *Acta physiol. scand.*, 1953, **29**, 377-380. [Nutrit. Res. Inst., Univ. Oslo.]

Two groups of rats of about 50 g. weight received a rachitogenic diet of, per cent., egg albumin 5, wheat flour of 75 per cent. extraction 88.8, dried brewer's yeast 2, CaCO₃ 2, NaCl 2, and FeCl₃ 0.2. Spinach was added, 0.5 kg. per 2 kg. diet. One group received in addition 1.5 I.U. vitamin D as cod liver oil. Another group received the same diet but with CaHPO₄ instead of CaCO₃ and no cod liver oil. After 16 days, X-ray examination showed florid rickets in the group on the first diet without cod liver oil, and normal calcification in the other 2 groups. Rats were killed after 16 and 19 days on the diets. On skin from those with unequivocal X-ray evidence of rickets, the O₂ consumption was measured in a Warburg apparatus, but no significant difference was found between the groups.—E. M. Hume.

1734

FEASTER, J. P., SHIRLEY, R. L., MCCALL, J. T. and DAVIS, G. K. ³²P distribution and excretion in rats fed vitamin D-free and low phosphorus diets. *J. Nutrition*, 1953, **51**, 381-392. [Nutrit. Lab., Agric. Exp. Stat., Univ. Florida, Gainesville.]

Weanling rats in groups of 44 were given a synthetic diet containing, per cent., Ca 0.4 and P 0.014. One group received 11.13 g. NaH₂PO₄, one group 3000 U.S.P.U. vitamin D₂, and one both per kg. ration. The Ca to P ratios were 28 : 1 and 1.6 : 1. After 10 days all the rats were given a dose of ³²P as inorganic phosphate by mouth or by intramuscular injection. Rats were killed subsequently after 15 min., 5 and 24 hr. and 4, 8, 14, 16 and 21 days. Total P and ³²P were estimated in the blood, tissues, urine and faeces.

The amount of total P in the liver, kidneys and muscle did not differ significantly in the 3 groups, being apparently maintained on the low-P diet at the expense of bone; in the femur it diminished steadily in the rats having the low-P diet and no vitamin D, but in the others it was maintained. Rate of deposition and turnover of ³²P in the femur was almost the same on all diets after oral administration, but after intramuscular injection it was throughout at a much lower level with the low-P diet. In muscle, liver, kidney and blood, the deposition of ³²P was greater after intramuscular administration; it was always higher with the low-P diet than with the other two, for which the results were nearly the same. In the urine of the rats on the low-P diet, the values for ³²P were about one-tenth those for the rats on the adequate-P diet. There was no evidence of any effect of vitamin D on the behaviour of the urinary or faecal P.

In older rats treated in the same way, radioautographs showed deposition of very little ³²P in the proximal end of the femur with the low-P diet compared with the others.—E. M. Hume.

1735

CLAASSEN, V. and WÖSTMANN, B. S. J. The uptake of injected radioactive phosphorus in the skeleton of the growing white rat. 1. The uptake of intravenously injected ³²P by rachitic and control animals during the first 24 hours. *Biochim. biophys. Acta*, 1953, **12**, 432-438. [Lab. Physiol. Chem., Municipal Univ., Amsterdam.] French and German summaries.

Rats were maintained from weaning on a modification of Steenbock and Black's rachitogenic diet containing, per cent., Ca 1.2 and P 0.3 with or without 14 I.U. vitamin D₂ given orally three times weekly. After 3 weeks they were given injections into the femoral vein of ³²P as NaH₂PO₄ and were killed at intervals of from 5 min. to 24 hr.

N.A. and R., April 1954

afterwards. Inorganic P and ^{32}P were estimated in the blood plasma and in the femur. Radioactive P could be detected in the femur of the rachitic and non-rachitic rats to about the same extent within 5 min. After 15 min. the uptake in the non-rachitic rats was the greater and it remained so to the end of the 24 hr.

It is considered that the initial uptake is by exchange and is comparable for rachitic and non-rachitic animals. Subsequently the incorporation of ^{32}P into bone is by deposition from the bloodstream, which occurs more actively in non-rachitic rats.—E. M. Hume.

1736

KIVENKO, S. and TITOV, A. Obogashchenie moloka vitaminom D. [Vitamin D enrichment of milk.] *Mol. Prom.*, 1953, 14, No. 8, 30-33. [Vses. Nauch.-Issled. Inst. Mol. Prom.]

A solution of irradiated ergosterol in refined vegetable oil was added to milk in the proportion of 1000 I.U. vitamin D to 1 litre. To obviate the difficulty of uneven distribution vitamin D was introduced in two steps. A concentrated emulsion of the solution of vitamin D, 154,000 I.U. per ml., was made with a small quantity of milk to form a basic mixture, and was added to the bulk milk which was then pasteurised, cooled and bottled. The same method was applied to dried milk. Basic mixtures prepared with condensed sterilised milk, with or without sugar could be used in schools and households for introducing vitamin D.

VITAMIN E

1737

NOBILE, S. and MOOR, H. Analysenmethode zur Bestimmung des Vitamins E in Lebens- und Futtermitteln. (Kolorimetrische Bestimmung nach Emmerie-Engel.) [Estimation of vitamin E in foods and feedingstuffs. Colorimetric estimation by the method of Emmerie and Engel.] *Mitt. Geb. Lebensmittel. Hyg.*, 1953, 44, 396-402. [Hoffmann La Roche Co., Basle.] French and English summaries.

The material under examination was minced, pulverised or homogenised, and heated with methanolic potash in the presence of Na ascorbate as a protective agent. Another portion of the same material was treated in the same way, but with addition of tocopherol as an internal standard. The unsaponifiable residues were extracted with light petroleum, and the vitamin E fraction was separated by chromatography on alumina for treatment with the FeCl_3 and $\alpha\alpha'$ -dipyridyl reagents. For milk and milk products the procedure was modified by including a preliminary extraction of the fat according to the Röse Gottlieb method.—T. Moore.

TAPPEL, A. L. The inhibition of hematin-catalyzed oxidations by α -tocopherol. *Arch. Biochem. Biophys.*, 1953, 47, 223-225. [Dept. Food Technol., Univ. California, Davis.]

The oxidation of colloidal linoleate in phosphate buffer, catalysed by haemoglobin or cytochrome c, was inhibited completely by α -tocopherol, *nor*-dihydroguaiaretic acid, propyl gallate or butylated hydroxyanisole. The inhibition by α -tocopherol of the co-oxidation of vitamin A and carotene with unsaturated fatty acids in emulsion systems with haemin was estimated by manometric oxygen absorption and spectrophotometry. The greater

the amount of tocopherol present, the greater was the protection of vitamin A and carotene.

McLEAN, J. R. and BEVERIDGE, J. M. R. **The prevention of liver necrosis by alpha-tocopherol, methionine, and cysteine by oral and parenteral routes.** *Canad. J. Med. Sci.*, 1953, **31**, 417-420. [Dept. Biochem., Queen's Univ., Kingston, Ont.]

Groups of 10 male rats of weight 55 g. were given a basal diet with or without daily supplements of 16 mg. DL-methionine, 40.3 mg. L-cysteine or 4.5 mg. α -tocopherol. The same amount of supplement as was given in the daily ration was administered by injection daily to other groups. The experiment was terminated after 105 days and the livers of the surviving rats were examined for necrosis. All the rats receiving no supplement died of liver necrosis in 39 days on the average. Of the rats which received methionine orally, 4 died, and of those which received it parenterally 7 died, after average periods of 70 and 61 days, respectively. Similarly, of those which received cysteine by mouth 7 died and of those which received it parenterally 8 out of 8 died, after average periods of 61 and 71 days, respectively. α -Tocopherol gave complete protection against liver necrosis whether given orally or parenterally.

BLAXTER, K. L. and SHARMAN, G. A. M. **Prevention and cure of enzootic muscular dystrophy in beef cattle.** *Nature*, 1953, **172**, 1006-1007. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Enzootic muscular dystrophy has been reported in suckling beef calves on from 15 to 25 per cent. of the farms in Inverness-shire that rear beef cattle. Sometimes 90 per cent. of the calves on a farm were affected. Observations were made on 4 groups of calves, each of 42 animals, which were spread over 20 farms. On each farm half the cows were given α -tocopheryl acetate before calving and half were not. The calves born in each group were again subdivided, half receiving the vitamin and half not. In the calves whose dams received no tocopherol, and which themselves were given no tocopherol after birth, there were 11 cases of dystrophy, of which 3 were fatal. Only 3 of the calves treated after birth were affected. Among the calves whose dams were treated, but which were not themselves treated, only 2 cases of dystrophy occurred, and there were none when calves were treated also after birth. If dystrophic calves were treated promptly with tocopherol they always recovered completely. Chemical estimation of tocopherol in the serum of calves born on farms where the disease was severe gave values of only 40 μ g. per 100 ml., compared with 150 μ g. in normal healthy calves in Ayrshire. The disease occurred almost always in calves born indoors in

spring to dams which had been housed since the previous autumn.—T. Moore.

1745

BLAXTER, K. L., BROWN, F. and MACDONALD, A. M. **The nutrition of the young Ayrshire calf. 13. The toxicity of the unsaturated acids of cod-liver oil.**

BLAXTER, K. L., BROWN, F., WOOD, W. A. and MACDONALD, A. M. **14. Some effects of natural and synthetic anti-oxidants on the incidence of muscular dystrophy induced by cod-liver oil.** *Brit. J. Nutrition*, 1953, **7**, 287-298; 337-349. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

13. Calves were given a basal diet of dried skimmed milk with a supplement of 2.5 mg. α -tocopheryl acetate daily to all except one. To the diet was added whole cod liver oil, or the unsaponifiable residue of it, or the saturated acids, or the unsaturated acids together, or the less unsaturated and the highly unsaturated acids separately. Four of the calves were given capsules of halibut liver oil.

The calves which were given whole cod liver oil or the total unsaturated acids developed severe muscular dystrophy. Slight dystrophy occurred with the highly unsaturated acids. The non-saponifiable residue and the saturated fatty acids had no effect. With the less unsaturated acids the calves did not develop dystrophy, but their musculature was pale. Muscles of both dystrophic and normal calves contained about the same amount of total tocopherols. Dystrophic muscles contained as much or even more tocopherol than contiguous, apparently normal muscles of the same animal. The mean creatine content of muscles of calves receiving whole cod liver oil, total unsaturated acids or highly saturated acids was less than of the animals given halibut liver oil. The experimental diets had little effect on the tocopherol content of other tissues. Peroxides could not be detected in lipids extracted from the tissues.

14. Calves were given a basal diet of dried skimmed milk and 1 fluid oz. cod liver oil daily with supplements of 200 mg. α -tocopheryl acetate daily by mouth, 400 mg. α -tocopheryl acetate every second day by intramuscular injection, 1.6 g. ascorbic acid daily by mouth in a single dose, 1.6 g. ascorbic acid daily by mouth in 2 doses, 3.2 g. ascorbic acid daily by intravenous injection, 0.4 mg. biotin daily by subcutaneous injection, 2.0 g. ethyl gallate daily by mouth or 1.0 g. methylene blue daily by mouth. Each animal received the equivalent of 7.5 mg. α -tocopherol from the cod liver oil and skimmed milk.

Muscular dystrophy was completely prevented by α -tocopheryl acetate given orally and by methylene blue. Considerable protection was given by α -tocopheryl acetate when injected, and

N.A. and R., April 1954

slight protection by ascorbic acid. Ethyl gallate and biotin provided no protection. The tocopherol content of the blood serum of the calves receiving cod liver oil and tocopherol by mouth rose rapidly from an initial value of 200 $\mu\text{g.}$ per 100 ml. to about 400, after which it remained fairly constant. The serum tocopherol of calves receiving tocopherol by injection fell rapidly to zero. Ascorbic acid given by mouth or injected had no effect on the rate of disappearance of tocopherol from the blood. There was no difference in the serum values between calves receiving cod liver oil alone, and those receiving ethyl gallate or methylene blue as well. Little difference was found in the tocopherol content of the tissues of calves receiving the several supplements. The value for serum tocopherol of the calves at the beginning of the experiment was closely correlated with the amount of colostrum they had been given, judged by the content of colostral globulins in the blood.

R. J. Ward.

1746

BLAXTER, K. L. **Muscular dystrophy.** *Vet. Rec.*, 1953, **65**, 835-837 (with discussion 837-838). [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

1747

NIELSEN, J., FISKE, A. N., PEDERSEN, A. H., PRANGE, I., SØNDERGAARD, E. and DAM, H. **The influence of feeding tocopherol to dairy cows on the yield of milk and milk-fat and on the tocopherol content and keeping quality of the butter.** *J. Dairy Res.*, 1953, **20**, 333-339. [Nat. Res. Inst. Animal Husb., Copenhagen.]

Cows in 2 groups of 9 were given a basal ration for 42 days. One group received a daily supplement of 2 g. α -tocopheryl acetate for the next 63 days and the other received only the basal ration. Both groups were then given the ration without supplement for a further 35 days.

The yield of milk and the percentage of fat in the milk were not affected by the tocopherol supplement. The butter produced from the milk

was assessed for quality and the peroxide number was estimated. After 14 days at 13° C. the butter from the milk of the cows receiving the supplement had an oily flavour and a peroxide value of 0.4 compared with 0.1 for butter from the milk of the cows receiving no supplementation.

In a second experiment when the 3 periods were of 35 days each, there was little difference in flavour and peroxide value. In the experimental period the tocopherol content of the butter rose from 10 to 12 $\mu\text{g.}$ per g. in the group without supplement to from 23 to 26 $\mu\text{g.}$ per g. in the group with supplement. Tocopherol supplementation did not result in an increase in the vitamin A and carotene content of the butter. Butterfat from the group without supplement was incorporated in a diet producing encephalomalacia in chicks; encephalomalacia did not develop, but the tocopherol content was insufficient to prevent white striation of the breast muscles.—T. Moore.

1748

PIANA, C. La mesoinosite potenzia l'azione mastoplastica della vitamina E? [**Meso-inositol as activator of the effect of vitamin E on the mammary gland.**] *Zootec. Vet.* 1953, **11**, 337-343. [Staz. Sper. Zootec., Univ. Milan.] English summary.

Virgin, castrated guineapigs were divided into 4 groups of 5 each. All received the same basal diet, and 3 groups were given, in addition per head daily, 10 or 20 mg. α -tocopherol or 10 mg. α -tocopherol with 20 mg. meso-inositol. The treatment began 20 days after castration. The animals were killed after 110 days, and the mammary tissue was examined histologically. Mammary development occurred in all 3 treated groups, and was greatest in the group given 20 mg. tocopherol alone. The effects in the other 2 treated groups were comparable. It was concluded that in the conditions of the experiment meso-inositol did not affect the action of high doses of vitamin E in stimulating mammary development.—T. D. Bell.

VITAMIN K

1749

CANDELLI, A. and POLITO, E. Ricerche sul meccanismo dell'azione antibatterica della vitamina K. [**Mechanism of the antibacterial action of vitamin K.**] *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 287-290. [Ist. Igiene, Univ. Perugia.]

Of the bisulphite and disulphonate of vitamin K, 2-methyl-1:4-naphthaquinone, both water-soluble, the former contains the quinone ring but the latter does not. The oxidation-reduction potential and the bacteriostatic action against *Sarcina rosea*, *Streptococcus pyogenes* and *Neisseria sicca* were estimated for the two salts. The disulphonate had the higher oxidation-reduction potential, but the

bisulphite was active in a concentration of 1 in 50,000 against the first 2 organisms and of 1 in 10,000 against the third, while the disulphonate was without activity in a concentration of 1 in 250 against any of them.—E. M. Hume.

DHYSE, F. G., FISHER, G. R., TULLNER, W. W. and HERTZ, R. Liver vitamin content and adrenal cortical function. *Endocrinology*, 1953, **53**, 447-450. [Nat. Cancer Inst., Bethesda, Md.]

Rats from which the adrenal glands had been removed were kept on a high-protein synthetic diet for 5 days. Food was then removed and 17 hr. later they received in successive small intraperitoneal injections a total of 250 mg. glucose alone or with 3 mg. cortisone acetate. One hour after the last injection the animals were killed and samples of liver were removed for estimation of glycogen and members of the vitamin B complex. Injection of cortisone with the glucose increased the liver content of glycogen to about 3 times the value when glucose alone was injected. The values for biotin, nicotinic acid, pantothenic acid, riboflavin, pyridoxine and folic acid in the liver were not substantially affected by adrenalectomy or by injection of cortisone.—W. Godden.

1755

MONTANARI, L. and MARCHETTI, M. Eliminazione urinaria di B₁ e B₂ nel ratto ipofisectomizzato. [Elimination of vitamin B₁ and riboflavin in the urine of hypophysectomised rats.] *Boll.*

Soc. ital. Biol. sper., 1953, **29**, 320-322. [Ist. Chim. Biol., Univ. Bologna.]

In rats weighing from 120 to 150 g., maintained on a complete diet, the amount of vitamin B₁ and of riboflavin eliminated in the urine, in mg. per 24 hr., ranged, respectively, from 0.214 to 0.375 and from 1.655 to 2.830. The corresponding values for rats after hypophysectomy were from 0.540 to 1.520 and from 2.420 to 9.120. The hypophysectomised rats ate, if anything, rather less than the normal rats.—E. M. Hume.

1756

HILL, D. C. and BRANTON, H. D. Failure of vitamin supplementation to improve growth on diets high in raw soybeans. *Poultry Sci.*, 1953, **32**, 882. [Dept. Nutrit., Ontario Agric. Coll., Guelph.]

Male Columbian Rock chicks which had received a commercial ration for 14 days were given a basal diet containing 50.75 per cent. of raw soya beans, with alfalfa meal, cerelose, minerals and an adequate vitamin mixture, supplemented with individual vitamins one at a time in amounts 20 times as great as the allowances recommended by the National Research Council. In no instance was growth improved; it was in fact depressed by pyridoxine, nicotinic acid or vitamin B₁₂. Addition of 1.365 g. DL-methionine per lb. basal diet significantly increased growth.

E. M. Cruickshank.

JACOBS, R. L., ELAM, J. F., QUISENBERRY, J. H. and COUCH, J. R. Dehydrated alfalfa leaf meal as a source of vitamins and unidentified factors for the mature fowl. *Poultry Sci.*, 1953, **32**, 812-816. [Dept. Biochem., Agric. Exp. Stat., College Station, Tex.]

White Leghorn pullets were given a diet of plant products with or without supplements of vitamin B₁₂ or alfalfa or both. Pantothenic acid, vitamin B₁₂ and citrovorum factor were estimated microbiologically in the egg yolks, and the clotting time of the blood was measured in day-old chicks from hens on the experimental diets. The hatching capacity of the eggs was increased by supplements of vitamin B₁₂, and was further increased when alfalfa was given in addition. Alfalfa alone aggravated the signs of vitamin B₁₂ deficiency and did not improve the hatching capacity of the eggs, but did increase the percentage of fertile eggs. Supplements of alfalfa meal raised the content of folic acid and citrovorum factor in the eggs, but did not affect the content of pantothenic acid and vitamin B₁₂. The clotting time of the chicks' blood was much reduced when alfalfa meal was added to the hens' basal diet.—E. M. Cruickshank.

WILCOX, A. C., MILLER, B. S. and MILNER, M. **Growth-promoting substances in white sugars from different sources of manufacture and their effect on fermentation.** *Cereal Chem.*, 1953, **30**, 427-434. [Dept. Flour and Feed Milling Indust., Kansas State Coll.]

Microbiological estimations with *Leuconostoc mesenteroides* of vitamins B₁ and B₆, nicotinic and pantothenic acids and biotin showed the presence of small amounts in dextrose from maize and in sucrose from sugar beet but not in sucrose from cane.

The effect of these sugars on the aerobic and anaerobic respiration of compressed baker's yeast was estimated manometrically. Sugars containing vitamins increased CO₂ production during anaerobic respiration, although the amounts present were insufficient or the number was incomplete for maximum production. Comparable effects were found in aerobic respiration. The sugars had no appreciable effect on the rate of fermentation of bread dough by the yeast.—V. R. Jackson.

1759

ADRIAN, J. Teneurs de l'oeuf de poule en riboflavine, niacine et acide pantothenique. Variabilité et corrélations. [The riboflavin, nicotinic acid and pantothenic acid content of hen's eggs. Variations and correlations.] *Ann. Agronom.*, 1952, 1952, No. 3, 17-29. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue.]

Estimations were made of riboflavin, nicotinic and pantothenic acids in hen eggs from a commercial source from April to mid-May, and in eggs from Rhode Island Red hens in batteries receiving for 3 weeks a controlled diet from about mid-June to mid-July. The eggs were plunged into boiling water and cooked for 10 min. before the estimations were made.

In the commercial eggs, the whole egg contained 4.6 µg. riboflavin per g., the ratio of the percentage in the yolk to that in the white being 1. Corresponding values for pantothenic acid were 19.8 and 4.6, and for nicotinic acid 0.6 and 0.39. Small eggs contained relatively more riboflavin and pantothenic acid than large eggs, but there was little difference in nicotinic acid concentration.

Hens under controlled conditions produced from 1 to 10 eggs each during the test; there was considerable variation in the vitamin content of both yolks and whites and of the ratios from hen to hen. The content of riboflavin and pantothenic acid in the yolks of the eggs was fairly constant in the eggs from any one hen, but the amount in the whites decreased as more eggs were laid. No similar observation was made for nicotinic acid. The average weight of the eggs was 46 g.; the contents in µg. per g. were riboflavin 4.4, nicotinic acid 0.6 and pantothenic acid 26.5; in the com-

mercial eggs riboflavin was slightly more concentrated in the yolks; the ratios for the other vitamins were the same as in the commercial eggs. Of the amount ingested by the birds, the percentage in the eggs was 11.4 for riboflavin, 0.065 for nicotinic acid and 25.2 for pantothenic acid.

FREY, K. J. **Effects of variety and location on thiamine, pantothenic acid, riboflavin, and niacin contents in oats.** *Quart. Bull. Michigan Agric. Exp. Stat.*, 1953, **36**, 13-17. [Dept. Farm Crops.]

Estimations were made of vitamin B₁, riboflavin, pantothenic acid and nicotinic acid in 5 varieties of oats grown in 4 locations in Michigan in 1949. Variety and location affected vitamin B₁ values significantly, differences with location amounting to 35 per cent. of the lowest value and with variety to 20 per cent. Similar differences were found for pantothenic acid values. Variety but not location caused significant differences in nicotinic acid values. For these 3 constituents the same varieties had the highest and the lowest contents. Differences between varieties and locations caused small though significant variations in riboflavin content. Environmental factors appeared to be additive and to affect all varieties in the same way.—V. R. Jackson.

1761

CLEGG, K. M. and LEWIS, S. E. **The vitamin-B content of foodstuffs fumigated with methyl bromide.** *J. Sci. Food Agric.*, 1953, **4**, 548-552. [Dunn Nutrit. Lab., Univ. Cambridge.]

Fifteen ml. of a solution containing 1 mg. per ml. of nicotinic acid, nicotinamide or vitamin B₁ in phosphate buffer at pH 7 was treated with 1900 mg. methyl bromide per litre for an hour at 25° C. and then with N₂ for an hour. Estimations were made of nicotinic acid by colorimetric, microbiological and fluorimetric methods and of vitamin B₁ by the thiochrome method. There was no significant loss of nicotinic acid or vitamin B₁, but a small significant loss of nicotinamide estimated by the colorimetric method but not by the other 2 methods. Ionisable bromide was found in the nicotinic acid and amide solutions but not in that of vitamin B₁.

Samples of milled wheat with different moisture contents were treated with methyl bromide at concentrations considerably in excess of those used in commercial practice, and then with N₂. There was no loss of nicotinic acid or amide, vitamin B₁ or riboflavin, except of the last in one sample.

There was no significant loss of nicotinic acid, riboflavin or vitamin B₁ from whole wheat, rice, barley, maize, groundnuts, peas or beans after treatment with methyl bromide.—V. R. Jackson.

VITAMIN B₁ (ANEURIN, THIAMINE)

1762

KIESSLING, K. H. and LINDAHL, G. **Paper chromatographic separation of thiamine and its phosphate esters.** *Ark. Kemi*, 1953, **6**, 271-272. [Inst. Zoophysiol., Univ. Upsala.]

Vitamin B₁ and its mono-, di-, and triphosphates were separated by paper chromatography. A solution was obtained in *n*-butyl alcohol saturated with water and containing 18 per cent. formic acid. With the descending technique on Whatman No. 1 paper, washed with 4 *N* HCl and oxine, the spots separated well when synthetic material was used. The spots were made visible by spraying with K ferricyanide in alkaline solution.—R. Marshall.

1763

PLETICHA, R. **Oszillographisch - polarographisches Studium des Vitamin B₁ in alkalischer Lösung. [Oscillographic - polarographic study of vitamin B₁ in alkaline solution.]** *Pharm. Zentralhalle*, 1953, **92**, 395-402; 435-439.

SHKODIN, A. M. and TIKHOMIROVA, G. P. **K polarografi tiamina. [Contribution to the polarography of vitamin B₁.]** *Biokhimiya*, 1953, **18**, 184-187. [Ukrain. Nauch.-Issled. Inst. Pishchevod. Prom., Kharkov.]

Vitamin B₁ could be estimated polarographically with 0.1 *N* KCl in water as a base electrolyte, a dropping mercury cathode and a saturated calomel anode. Preliminary experiments showed that E₂ became more negative with increasing pH from -1.25 at pH 6 to -1.35 at pH 8.5; in 50 per cent. aqueous ethanol solution E₂ was displaced positively from -1.25 to -1.125; E₂ was -1.36 in a 70 per cent. acetone and water medium. The method could be used to estimate vitamin B₁ in substances such as sugars containing only that vitamin, or in products containing other vitamins, including vitamins A, C and D and riboflavin, nicotinic acid and nicotinamide. Vitamin C was first oxidised with permanganate. The method of additions was used. Concentrations of 10⁻³ to 10⁻⁵ *M* could be determined.—W. Hughes.

1765

BOUMAN, J. **A new method for the determination of thiamine in urine.** *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 83-85. [Lab. Physiol. Chem., Nederlands Inst. Volksvoeding, Amsterdam.] German and French summaries.

Interference by the factor F₂ in the estimation in urine of vitamin B₁ as thiochrome was eliminated by oxidation of the urine in acid solution with K ferricyanide, removal of excess ferricyanide with ascorbic acid and extraction with *isobutanol* in

acid solution, followed by the usual method for oxidation of vitamin B₁ to thiochrome. More K ferricyanide was needed than for oxidation to thiochrome only. It is claimed that complete elimination of the interfering substance was obtained.—V. R. Jackson.

1766

FARRER, K. T. H. and HOLLENBERG, W. C. J. **Adsorption of thiamine on glassware.** *Analyst*, 1953, **78**, 730-731. [Kraft Foods, Ltd., Melbourne.]

Thirty ml. of a solution containing 0.1 µg. vitamin B₁ per ml. were swirled for 20 sec. in a number of similar glass vessels in succession. The vessels included flasks and cylinders, stoppered or calibrated, some new and some in constant use. Vitamin B₁ was estimated by the thiochrome method.

Percentage loss of vitamin B₁ ranged from 21 after passage through 5 calibrated 250 ml. flasks to 44 after passage through 6 stoppered flasks of 25 ml. capacity. Washing the glassware with alkaline ferricyanide resulted in recovery of 75 per cent. of the vitamin B₁ lost, showing that most of the loss was by adsorption on the glass. Thiochrome was not adsorbed on glass, nor was vitamin B₁ in highly acid solutions of the pure vitamin or of yeast extract.

Bird's procedure (*N.Z. J. Sci. Technol.*, 1949, **30**, 344) of washing glass with alkali every 3 months is recommended for preventing loss. It prevented also the removal from the glass of fluorescent material other than thiochrome by the mixture of ethanol and butanol used in the thiochrome method.—V. R. Jackson.

1767

REED, L. J. **Metabolic functions of thiamine and lipoic acid.** *Physiol. Rev.*, 1953, **33**, 544-559. [Biochem. Inst., Univ. Texas, Austin.]

FERRARI, G. **Comportamento del piruvato del sangue nella ipoalimentazione. [Behaviour of blood pyruvate in undernutrition.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 290-292. [Ist. Fisiol., Univ. Pavia.]

Experiments with rats weighing from 55 to 65 g., deprived and not deprived of vitamin B₁ and some of them subjected to paired feeding, showed that only deprivation of vitamin B₁ had any effect in causing a rise of blood pyruvic acid; the values in mg. per 100 g. blood were for the deprived 3.39, and for the normal and pair-fed animals 1.51 and 1.46, respectively.—E. M. Hume.

1769

PECORA, L. J. and HIGHMAN, B. **Organ weights and histology of chronically thiamine-deficient rats and their pair-fed controls.** *J. Nutrition*, 1953, **51**, 219-229. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

Weanling male albino rats received a commercial diet for 2 weeks and then were divided into 3 groups and received a diet deficient in vitamin B₁ with 7 µg. three times weekly, or the diet with adequate vitamin B₁ to appetite or with intake restricted to that of the partially deprived rats. After 63 days the first group was totally deprived of vitamin B₁, and from 7 to 10 days later the animals were killed and the organs were removed. Some normal rats were killed at about 33 days of age, when their weight was the same as that of the deprived rats, and some rats were killed in all groups when the deprived rats reached their maximum weight, at about 57 days of age.

The deprived rats grew normally for 4 weeks, then for 7 weeks lost weight amounting to 40 per cent. of their maximum weight. Before loss of weight began the ratios of organ weight to bodyweight were similar in the 3 groups, except for liver and spleen, for which the ratios were considerably smaller in the groups deprived of vitamin B₁ or food than in those with adequate diet. Subsequently, in the organ to bodyweight ratios for heart, adrenal glands, testes, pituitary gland, liver, spleen and brain there was no difference between rats deprived of vitamin B₁ and those with restricted food intake, which showed that the decreased size of the organs was due to inanition rather than to vitamin deficiency. The kidney to bodyweight ratio was considerably greater in the deprived rats than in those with restricted intake, indicating an additional effect of vitamin B₁ deficiency over that of inanition.

The absolute loss in weight of organs was similar in groups deprived of vitamin B₁ or food, except for the kidneys of the former group, which lost little. The weight loss of the organs was not proportional to the loss of bodyweight as it is in starvation. It is concluded that comparison could best be made between 100-day-old deprived rats and 57-day-old normal rats, in which the brain and adrenal weights were the same, and the weights of other organs, particularly the liver and spleen, were less in the deprived rats.

A small number of vitamin-deficient rats developed lesions of the auricular myocardium. The groups deprived of vitamin B₁ and those with restricted food intake showed depletion of lymphocytes in the spleen, diminished haemopoietic activity, haemosiderin deposits in the liver and spleen, and atrophy of some organs due to shrinkage of parenchymal cells.—V. R. Jackson.

ABBATI, A., CAVALLI, G., MARTINELLI, M. and POPPI, A. L'azione del citocromo c e della cocarbossilasi sulle modificazioni istologiche indotte nel ratto albino dalla carenza di tiamina. [The action of cytochrome c and of cocarboxylase on the histological changes induced in the white rat by vitamin B₁ deficiency.] *Arch. Sci. biol., Bologna*, 1953, **37**, 340-353. [Ist. Patol. Speciale Med., Univ. Bologna.]

Of 25 male rats weighing from 80 to 90 g., one group received a complete diet, one received water only, and one received a diet deficient in vitamin B₁. In the last group 5 rats were given 40 mg. cytochrome c, and 5 were given 200 mg. cocarboxylase, both per kg. bodyweight, injected intraperitoneally every 5 days. The experiment lasted 90 days. The rats having water alone lived only 15 days. In the deprived rats growth ceased and signs of deficiency appeared, but those given cytochrome c or cocarboxylase behaved like those having the complete diet. Histological and histochemical examination confirmed the results.

WILWERTH, A. M. and MEITES, J. **Effects of cortisone on thiamine-deficient young rats.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 872-875. [Dept. Physiol. Pharmacol., Michigan State Coll., East Lansing.]

Young male rats received a semi-synthetic diet containing no vitamin B₁ for 10 days and then for 12 or 18 days a dietary supplement of up to 20 mg. vitamin B₁ per kg. diet with or without 1 mg. cortisone acetate given subcutaneously. Growth and appetite were reduced in all the rats after 10 days' depletion, but both were restored in those given 1 mg. vitamin B₁ per kg. Those deprived for longer lost further weight, especially if given cortisone, although appetite was not further reduced. Addition of 1 mg. vitamin B₁ per kg. to the diet of deprived rats receiving cortisone partly overcame the lowering of growth rate, and eliminated gross signs of vitamin deficiency, including muscular inco-ordination and priapism. In a test with younger rats deprived for a longer period cannibalism appeared in the group receiving cortisone alone. If the vitamin supplement was 5, 10 or 20 mg., the inhibition of growth caused by cortisone was almost completely counteracted. Rats with restricted intake and 20 mg. vitamin B₁ per kg. diet and cortisone had a low bodyweight but no gross sign of deficiency. It is considered that the minimum protective dose of vitamin B₁ should be increased about 5 times to counteract the effect of injecting 1 mg. cortisone daily.

LILLY, V. G., BARNETT, H. L. and ANDERSON, B. G. The effects of allithiamine on some thiamine-requiring organisms. *Science*, 1953, **118**, 548-549. [Dept. Plant Pathol., W. Virginia Univ., Morgantown.]

The activity was estimated of allithiamine for 5 fungi requiring vitamin B₁ for normal growth. The fungi were incubated at 20° C. in media containing glucose and asparagine, and insufficient amounts of vitamin B₁ and allithiamine. Growth was estimated by weighing the dried mycelium.

Allithiamine was more active than vitamin B₁ for *Endoconidiophora fimbriata*, *Mucor ramannianus* and *Phycomyces blakesleeanus*, and less active for *Schizothecium longicolle* and *Thielaviopsis basicola*. Aqueous extracts were prepared from mycelium of *P. blakesleeanus* grown with allithiamine or vitamin B₁, and by comparison of the effects on the growth of fungi of these extracts before and after treatment with alkaline ferricyanide and CNBr which destroy allithiamine completely but vitamin B₁ only partially, it was con-

cluded that *P. blakesleeanus* converted allithiamine to vitamin B₁.

Experiments with young rats made deficient in vitamin B₁ showed that allithiamine could replace vitamin B₁ and gave good growth.—V. R. Jackson.

KAUNITZ, H., WIESINGER, H. and SLANETZ, C. A. Probleme des Riboflavinstoffwechsels. [Problems of riboflavin metabolism.] *Wien. klin. Wochenschr.*, 1953, **65**, 709-713. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

The problem of riboflavin metabolism is reviewed with particular reference to recent studies with rats having diets containing varying proportions of protein and fat. The rapid onset of corneal vascularisation with a diet containing 5 per cent. casein and 20 per cent. lard was not delayed by administration of riboflavin, but with higher proportions of casein the development of the lesions was delayed. The inference that riboflavin is

N.A. and R., April 1954

intimately concerned in protein metabolism is discussed with other probable roles of the vitamin.

1779

MILLER, C. O., ELLIS, N. R., STEVENSON, J. W. and DAVEY, R. **The riboflavin requirement of swine for reproduction.** *J. Nutrition*, 1953, **51**, 163-170. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Young sows received diets containing 0.55, 0.83, 1.25 or 1.65 mg. riboflavin per lb. Sufficient protein was included for gestation and lactation. The sows were mated at 9 months and all but the first group were re-mated after the first litter was weaned.

The smallest amount of riboflavin proved inadequate for reproduction; 3 of 7 sows died, 3 more failed to conceive and 1 produced a litter which died within 48 hr. Among the other groups no difference was apparent in the sows, but those receiving 0.83 mg. vitamin per lb. diet produced litters of low viability and weighing significantly less than those receiving 1.25 mg. There appeared to be little improvement in the performance of those receiving 1.65 mg. per lb. over those with 1.25 mg. Second litters were heavier than first litters in these 2 groups but less in those receiving 0.83 mg. per lb., showing that the effects of deficiency were cumulative. A minimum of 1.25 mg. riboflavin per lb. diet is recommended for breeding sows.—V. R. Jackson.

1780

RICHERT, D. A. and WESTERFELD, W. W. **Some interrelations of dietary protein, molybdenum, riboflavin and calories on liver and intestinal xanthine oxidase.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 726-729. [Dept. Biochem., Med. Coll. State Univ. New York, Syracuse.]

Weanling male albino rats were divided into 4 groups and given a diet containing 24 per cent. casein and 65 per cent. glucose with both riboflavin and Mo (control group), either riboflavin or Mo, or neither. Other requirements were met. A fifth group received the control diet but with intake restricted to 23 per cent. of that of the control group and a sixth group a diet containing 96 per cent. casein and 4 per cent. salt mixture, all vitamins and Mo, with intake restricted to 25 per cent. of that of the control group. The last group was then receiving the same amount of energy daily as the fifth group and the same protein daily as the control group. After from 2 to 3 weeks estimations were made of xanthine oxidase in the liver and intestine.

The omission of riboflavin or Mo or both from

the diet containing 24 per cent. casein had no effect on liver xanthine oxidase. Omission of Mo with or without riboflavin removed the enzyme from the intestine, and deprivation of riboflavin with Mo present reduced the concentration to half that of rats receiving riboflavin and Mo. The oxidase-dehydrogenase activity of the enzyme in the liver and intestine was not affected by either deficiency. Restricted intake of the diet containing 24 or 96 per cent. casein had no effect on liver or intestinal xanthine oxidase.

The intake of protein appeared to have the greater effect on the liver enzyme and of Mo on the intestinal enzyme.—V. R. Jackson.

DIETRICH, L. S. and SHAPIRO, D. M. **Combination chemotherapy of cancer: potentiation of carcinostatic action of 8-azaguanine by a riboflavin analog.** *Cancer Res.*, 1953, **13**, 699-702. [Dept. Biochem., Coll. Phys. Surg., Columbia Univ., New York.]

Mammary adenocarcinomata were transplanted into the axillary region of female mice aged from 2 to 3 months. The effect was recorded of injecting, per kg. bodyweight, 50 mg. 8-azaguanine and 60 mg. flavotin simultaneously or in succession. Methods of estimation and analysis were described previously (Abst. 1597, Vol. 23).

The carcinostatic action of 8-azaguanine was enhanced when flavotin was given 1 hr. previously; if the substances were given simultaneously or the flavotin after the purine there was no effect. In tests *in vitro*, animals were killed 1 hr. after the last injection of flavotin, homogenates were made of tumours and livers, and guanase and xanthine oxidase activities were estimated. The addition of flavotin to the liver homogenates during incubation had no effect on the activity of guanase or xanthine oxidase activity. No xanthine oxidase was found in tumours from animals treated with flavotin but in tumours from untreated animals there were measurable amounts, one-eighth to one-tenth of that in the liver.

It was concluded and confirmed that flavotin inhibited xanthine oxidase. It was observed that guanase activity was inhibited by increasing amounts of xanthine in a phosphate or borate medium, and it is suggested that flavotin enhances the carcinostatic action of 8-azaguanine by inhibiting tumour xanthine oxidase and, therefore, indirectly inhibiting guanase, which is responsible for the deamination of 8-azaguanine to 8-azaxanthine, a non-carcinostatic compound.

NICOTINIC ACID (NIACIN)

1782

SWEENEY, J. P. **Report on a chemical method for nicotinic acid.** *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 856-857. [Food and Drug Admin., Dept. Health, Washington, D.C.]

After further collaborative trials of the sulphanilic acid method previously described (*ibid.*, 1951, **34**, 99; 380) it is recommended that the method be made official.—W. Godden.

1783

SWEENEY, J. P. and HALL, W. L. **The use of ion exchange resin in the quantitative chemical differentiation between nicotinic acid and nicotinamide.** *J. Assoc. Off. Agric. Chem.*, 1953, **36**, 1018-1022. [Food and Drug Admin., Dept. Health, Washington, D.C.]

The anion exchange resin Amberlite IRA-400, which had been found by Kato and Shimizu (*Abst.* 3421, Vol. 21) not to adsorb nicotinamide, was found to adsorb nicotinic acid, which could be eluted subsequently with *N* HCl. The nicotinamide and nicotinic acid could be estimated with CNBr and sulphanilic acid as reported previously (*Abst.* 3423, Vol. 21). One part of nicotinamide could be estimated accurately in the presence of 100 parts of nicotinic acid, and 1 part of the acid in the presence of 100 parts of the amide provided a correction was applied for slight hydrolysis of nicotinamide by the resin.

CHAUDHURI, D. K. **Estimation of nicotinic acid in urine.** *Ann. Biochem. Exp. Med.*, 1952, **12**, 119-122. [Dept. Appl. Chem., Nutrit. Res. Unit, Indian Council Med. Res., Calcutta.]

Nicotinic acid was estimated in normal or diabetic urine by digesting with concentrated HCl for 45 min. over a water bath, centrifuging and extracting the supernatant fluid with *isobutanol*. The water phase was heated with 4 per cent. KMnO_4 , cooled and brought to pH 6.6, and a mixture of ethanol and water was added to make up the required volume. After further cooling in a refrigerator, a yellow colour was developed with *p*-aminobenzoic acid in the colourless extract, and estimated in a photo-electric colorimeter. The method was found specific for nicotinic acid and amide with recoveries ranging from 98 to 104 per cent. Values for 6 estimations on a single sample ranged from 15.5 to 20.3, average 17.1 μg . in 20 ml.—V. R. Jackson.

QUAGLIARIELLO, G. and PORCELLATI, G. **Sulla amidazione enzimatica dell'acido nicotinico. [Enzymic conversion of nicotinic acid to amide.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 273-275. [Ist. Chim. Biol., Univ. Naples.]

Kidney and liver tissue from rats of weight about 500 g. was incubated in modified Ringer solution containing 0.0012 *M* ammonium nicotinate, through which a mixture of 95 per cent. O_2 and 5 per cent. CO_2 was passed. For measuring the amount of nicotinamide formed, a chemical method is described which is considered to give much more accurate results than paper chromatography. Little nicotinamide was found with sodium compared with ammonium nicotinate.

HUGHES, D. E. and WILLIAMSON, D. H. **The deamidation of nicotinamide by bacteria.** *Biochem. J.*, 1953, **55**, 851-856. [Med. Res. Council. Unit Res. Cell Metabol., Univ. Sheffield.]

The deamidating enzyme was present in washed cells and cell-free extracts of lactobacilli, including *L. casei*, *L. delbrueckii*, *L. helveticus* and particularly *L. arabinosus* and *L. bulgaricus*. The reaction was shown to be a stoichiometric hydrolysis giving nicotinic acid and ammonia, the rate of reaction being proportional to the enzyme concentration. Nicotinamide was decomposed completely and the reaction was not inhibited by high concentrations of nicotinic acid or ammonia; it did not depend on the concentration of nicotinic acid or its derivatives or on the absence of glucose from the

N.A. and R., April 1954

medium in which the cells were grown or on its pH or on the age of the cells. Nicotinamide was not formed when the enzyme preparations were incubated with ammonium nicotinate, with or without adenosine triphosphate, glutamine, Mg and Mn.

The optimum range of pH for the enzyme was from 4.5 to 8.0; below 4.5 activity decreased rapidly. The apparent Michaelis constant was 0.0015 M. The enzyme was specific for deamidating nicotinamide and could be used for estimating free nicotinamide in tissues, but the method was less convenient than chemical methods. Freshly washed cells lost up to 25 per cent. of their activity after 7 days at 2° C., but extracts were stable. Dialysis against water, phosphate buffer at pH 7 or acetate buffer at pH 5 caused no loss of activity. Heating or treatment with ethanol, ammonium sulphide or sulphate caused loss of activity. The enzyme was inhibited by ions of heavy metals but not by substances related to nicotinamide, phenol- or sulphonophthaleins, acridine, atebine or euflavine or several other compounds.

Other organisms tested included *Staphylococcus albus* and *aureus*, *Streptococcus haemolyticus*, *Clostridium welchii*, *Bacterium coli*, *Acetobacter suboxydans*, *capsulatus* and *aceti*, *Aerobacter aerogenes* and *Pseudomonas fluorescens*. Only one strain of *Staph. albus* deamidated nicotinamide significantly.

The use of the enzyme for identifying and estimating pyridine derivatives is discussed.

BERA, G. N. **Effects of niacin and nicotinamide on blood sugar.** *Amer. J. Physiol.*, 1953, **175**, 296-298. [Dept. Physiol., Presidency Coll., Calcutta.]

Nicotinic acid or nicotinamide or adrenaline was injected into the muscle of adult rabbits. Blood sugar rose to a maximum within 1 hr. after injection of each of them. The effect of nicotinic acid and nicotinamide resembled that of adrenaline, and the adrenaline content of the blood was raised when nicotinic acid or amide was injected. The presence of adrenaline was further demonstrated by a rise of blood pressure after injection into a cat of blood from a rabbit which had received nicotinic acid.—A. M. Copping.

DE FRANCISCIS, G. and MARSICO, F. **Il comportamento del ferro serico dopo iniezione endovenosa di vitamina PP in cani normali e splenectomizzati. [Behaviour of iron in the serum after intravenous injection of vitamin PP in normal and splenectomised dogs.]** *Boll. Soc. ital. Biol. sper.*, 1953, **29**, 267-269. [Ist. Fisiol. Vet., Univ. Naples.]

Vol. 24, No. 2

Blood was taken from 5 dogs of bodyweight about 7 kg., fasting for 12 hr., before and 4, 30, 60, 120, 180 and 240 min. after intravenous injection of 3 mg. vitamin PP (Nicotene Lepetit), and serum proteins and Fe were estimated. Three of the animals were splenectomised, and the experiment was repeated from 15 to 45 days later. Before and after splenectomy, injection of the vitamin caused an immediate severe fall in serum Fe and a subsequent rise. In the intact dogs the normal value was restored within 60 min., but in the splenectomised dogs the rise was much less and normal values had not been attained after 240 min. Serum albumin fluctuated after the injection, and there was a marked fall in the albumin: globulin ratio. The behaviour of the serum proteins was not affected by splenectomy.

SLINGER, S. J., PEPPER, W. F., MORPHET, A. M. and EVANS, E. V. **Effect of penicillin on the niacin requirement of turkeys and a carry-over effect of penicillin from dams to progeny.** *Poultry Sci.*, 1953, **32**, 754-762. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Bronze-breasted poults of both sexes were given for 4 weeks a practical rearing diet containing, per lb., 11.7 mg. nicotinic acid, supplemented with graded amounts of nicotinic acid with or without 10 p.p.m. of procaine penicillin. Growth was not increased by adding nicotinic acid in absence of penicillin; in its presence slightly better growth was obtained with from 16.7 to 21.7 mg. nicotinic acid per lb. feed than with the unsupplemented basal diet. In a second experiment, poults received for 24 weeks basal diets with or without 7.5 mg. added nicotinic acid and with or without penicillin. Penicillin improved growth and increased efficiency of feed utilisation whether the diet contained added nicotinic acid or not. The presence of penicillin in the diet of the dams adversely affected the growth of the poults. No perosis occurred in the females; in the males it was completely prevented up to 16 weeks of age, and partly at 24 weeks, by nicotinic acid and penicillin together, but not by either alone.

VITAMIN B₆ (PYRIDOXINE, ADERMIN)

1795

SNYDER, J. Q. and WENDER, S. H. **The separation and determination of pyridoxine, pyridoxal and pyridoxamine by paper chromatography and microbiological assay.** *Arch. Biochem. Biophys.*, 1953, **46**, 465-469. [Dept. Chem., Univ. Oklahoma, Norman.]

Stock solutions of the hydrochlorides of pyridoxine, pyridoxal and pyridoxamine were spotted on to strips of paper and developed; one-dimensional development in the dark in sealed containers at constant temperature was employed, with a mixture of *n*-amyl alcohol, acetone and water and the ascending technique. When the paper was sprayed with a solution of 2:6-dichloroquinone-chloroimide in benzene, and then saturated with vapour from hot ammonium chloride solution, blue spots characteristically placed for the 3 substances under test were obtained. For the quantitative work a sprayed paper could be used to show the regions covered by the 3 test substances on unsprayed papers. The papers could then be cut up and water solutions made of the 3 test substances in the paper sections. Estimation was by a method with *Saccharomyces carlsbergensis* A.T.C.C. 9080.—R. Marshall.

MUSINI, A. and TENCONI, L. T. **Studio parallelo di lesioni anatomo-cliniche (oculari) e biochimiche (metabolismo del triptofano) in ratti carenti di axeroftolo o di piridossina. [Parallel study of lesions, structural (eye) and biochemical (metabolism of tryptophan), in rats deprived of vitamin A or pyridoxine.]** *Acta vitaminol.*, 1953, **7**, 200-212. [Div. Oculistica, Osp. Maggiore, Milan.] English, French, German and Spanish summaries.

One series of rats aged 47 days and weighing from 90 to 105 g. received a diet deficient in vitamin A, and another received one deficient in vitamin B₆. In each series, one group of 9 rats received the missing vitamin from the start, one received it from the fifth week of deprivation, and one did not receive it at all. The eyes of all the animals were examined regularly with the slit-lamp. After death the eyes were fixed in formalin for histological examination. Urine was collected for 24 hr. after tests with a single dose of L-tryptophan, 500 mg. per kg. bodyweight, and xanthurenic acid and kynurenine were estimated by paper chromatography. In the rats deprived of vitamin B₆, the amounts of xanthurenic acid and kynurenine

excreted were much increased and fell again when pyridoxine was given, but in the rats deprived of vitamin A there was no change. The macroscopic and histological appearance of the eye lesions is described, and it is pointed out how closely the effects on the eye of the two deficiencies resemble one another.—E. M. Hume.

BEATON, J. R., BEARE, J. L., BEATON, G. H. and MCHENRY, E. W. **Studies on vitamin B₆. 4. The effect of vitamin B₆ on protein synthesis and maintenance in the rat.** *J. Biol. Chem.*, 1953, **204**, 715-719. [Dept. Pub. Health Nutrit., Sch. Hyg., Univ. Toronto.]

Groups of rats were given a purified diet containing 20 per cent. casein and 20 per cent. fat. Some received no pyridoxine and others had 50 µg. daily. The food intake of all the animals was restricted to the amount eaten by those having no vitamin B₆. In a study of the synthesis of liver protein by measuring tissue regeneration after partial hepatectomy all animals received deoxypyridoxine. In rats deprived of vitamin B₆ there was no apparent change in the amount of total crude fatty acid, protein or moisture in the liver whether part of the liver was excised or not. In rats which had had part of the liver excised neither the amount nor the constituents of the regenerated tissues differed in groups with and without vitamin B₆. The glutamic acid dehydrogenase activity of the livers was similar in all groups. The findings are considered as evidence that lack of vitamin B₆ does not in the rat affect the synthesis of cellular protein or the maintenance of liver-enzyme protein.—A. M. Copping.

BLASCHKO, H., DATTA, S. P. and HARRIS, H. **Pyridoxin deficiency in the rat: liver L-cysteic acid decarboxylase activity and urinary amino-acids.** *Brit. J. Nutrition*, 1953, **7**, 364-371. [Dept. Pharmacol., Univ. Oxford.]

Weanling rats received a diet similar to that described by Carpenter *et al.* (Title 427, Vol. 19) containing succinylsulphathiazole and with or without pyridoxine. Two groups received the vitamin, one of the same age as the deprived rats but considerably heavier, and one of the same weight but younger. The deprived animals ceased to gain weight in the third week, their coats were poor and skin lesions appeared. Urine was collected after from 9 to 47 days for chromatographic examination. Rats were killed immediately after urine collection and L-cysteic acid decarboxylase activity (Title 4913, Vol. 19) was estimated in the liver.

The urine of rats receiving pyridoxine contained taurine, and also glycine, alanine and other amino-acids in variable small amounts. The urine of deprived rats contained glycine and a substance provisionally identified as ethanolamine phosphate; taurine was found in some samples but the incidence decreased with length of deprivation. L-Cysteic acid decarboxylase activity was present in the livers of rats given pyridoxine but not of deprived rats. When livers of non-deprived male rats, which had greater enzyme activity than those of female rats, were incubated with and without L-cysteic acid, the enzymic decarboxylation of L-cysteic acid was shown to produce taurine and CO₂. The appearance of other amino-acids during incubation was probably due to autolysis of liver tissue.

Two rats were deprived of riboflavin; urine from both contained taurine but no ethanolamine phosphate and both livers possessed L-cysteic acid decarboxylase activity.—V. R. Jackson.

BUTLER, L. C. and MORGAN, A. F. **Eosinopenic responses of pyridoxine-deficient rats to epinephrine, adrenocorticotrophic hormone and hypoxia.** *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 655-659. [Dept. Home Econ., Univ. California, Berkeley.]

The eosinopenic response, induced by saline, adrenaline, adrenocorticotrophic hormone, fasting, or low oxygen tension, was measured in adult male rats given a diet with or without pyridoxine. Vitamin B₆ deficiency was enhanced by inclusion of deoxypyridoxine in the diet of the deprived rats, and one group given pyridoxine was restricted in food intake so that their weight loss was that of the deprived group. The non-deprived rats whose food was unrestricted gained on an average 1 per

cent. in weight during the 8 weeks of the test; the other two groups lost 29 per cent. The eosinopenic response at 4, 7 and 8 weeks to all the treatments in intact rats and in a group of hypophysectomised rats treated with adrenocorticotrophic hormone was of the same order whether pyridoxine was given or not, and whether the animals lost weight or gained slightly.—A. M. Copping.

1802

MORRIS, H. P., DUNN, T. B. and WAGNER, B. P. **Influence of gonadotrophin on pyridoxine-deficient and diet-restricted female mice.** *J. Nat. Cancer Inst.*, 1953, **14**, 493-511. [Nat. Cancer Inst., Bethesda, Md.]

Weanling female mice were given a synthetic diet with or without pyridoxine, and the food of some having supplements was restricted to that of those without. Some animals for from 3 to 10 weeks received injections of gonadotropin from the second or seventh week. The hormone had little effect on food intake or weight gain, but increased the size of the ovaries; the increase was greater in the deprived mice than in those having pyridoxine. In both deprived and non-deprived the mammary glands showed proliferation of the duct epithelium in harmony with the ovarian changes. In the deprived mice little degeneration of the X-zone of the adrenal glands occurred, and the degeneration was only partial in non-deprived mice with restricted food intake. When gonadotropin was given to these animals the X-zone disappeared but no lipid was formed.

Gonadotropin had no apparent effect on the blood picture, which was characterised by low Hb values and low erythrocyte and lymphocyte counts.—A. M. Copping.

1803

BEATON, G. H. and MCHENRY, E. W. **Vitamin B₆ levels in rat tissues.** *Brit. J. Nutrition*, 1953, **7**, 357-363. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Rats of the Wistar strain were given a diet lacking vitamin B₆ and containing 20 per cent. casein and 20 per cent. maize oil, with or without addition of deoxypyridoxine. In an experiment in which the food intake of all groups was restricted to that of the most severely deprived rats, the concentration of vitamin B₆ in the livers of rats given deoxypyridoxine with or without added pyridoxine was not less than in rats of corresponding groups with no antivitamin. In a further test, groups of rats were killed at intervals, and it was found that when a low concentration of vitamin B₆ was established in the tissues, administration of deoxypyridoxine reduced the time till appearance of the characteristic lesions of vitamin B₆ deficiency. The presence of deoxypyridoxine in the

diet did not prevent recovery from acute deprivation when pyridoxine was given. The vitamin B₆ content of the heart, liver and kidney and of the whole carcass was estimated with *Saccharomyces carlsbergensis*. From the relation between the vitamin B₆ content of the whole carcass and that of the liver, it appeared that in deficiency transfer might occur from extrahepatic sources into the liver. The vitamin B₆ content of the liver was found more useful than that of the heart or kidney for indicating the state of vitamin B₆ nutrition. At the same time, it was observed that the liver became saturated with vitamin B₆ when the amount in the diet was not enough to support maximum growth.—A. M. Copping.

1804

BEARE, J. L., BEATON, J. R., SMITH, F. I., WHITE, J. M. and MCHENRY, E. W. **Effects of adrenalectomy and of adrenal cortical extract in pyridoxine-deprived and supplemented rats.** *Amer. J. Physiol.*, 1953, **175**, 21–24. [Dept. Pub. Health Nutrit., Univ. Toronto.]

The effect of giving adrenal cortical extract to adrenalectomised rats having a synthetic diet lacking vitamin B₆ and containing 20 per cent. casein was examined by studies of blood and tissue composition and of N output in faeces and urine. Removal of the adrenal glands prevented the occurrence of severe skin lesions in rats deprived of vitamin B₆ and given deoxypyridoxine, but did not alter the characteristic metabolic disturbances (*cf.* Abst. 2930, Vol. 23). The results of administering adrenal cortical extract with and without pyridoxine showed that no significant change in the metabolic pattern of vitamin B₆ deficiency was induced by the cortical hormones. The hormones were apparently not concerned in the utilisation of pyridoxine by the rat.—A. M. Copping.

PANTOTHENIC ACID

1806

SCHWEIGERT, B. S. and GUTHNECK, B. T. **Liberation and measurement of pantothenic acid in animal tissues.** *J. Nutrition*, 1953, **51**, 283–293. [Div. Biochem. Nutrit., American Meat Inst. Found., Chicago, Ill.]

Enzyme preparations suitable for liberating pantothenic acid from co-enzyme A and from animal tissues were investigated. Of 6 different preparations from pigeon liver, pig kidney, lamb kidney and intestinal phosphatase, a mixture of intestinal phosphatase and a Dowex-treated pig-kidney extract was finally adopted as giving the best extraction of pantothenic acid. The results obtained were generally higher than those previously obtained by digestion with Mylase P.

1805

SHAPIRO, D. M., SHILS, M. E. and DIETRICH, L. S. (with ATTI, A., BORRIES, E., FINE, A., FUGMANN, R., HAYWORTH, P. and ZANAR, E.) **Quantitative biochemical differences between tumor and host as a basis for cancer chemotherapy. 1. Vitamin B₆.** *Cancer Res.*, 1953, **13**, 703–708. [Dept. Surg., Coll. Phys. Surg., Columbia Univ., New York.]

Mice aged from 2 to 4 months, receiving an adequate diet to appetite, were implanted in the axillary region with mammary adenocarcinoma. Daily injections of testosterone, deoxypyridoxine or both were started at intervals after implantation. Some animals received 8-azaguanine as well. The test lasted about 21 days. Estimations were made of vitamin B₆ microbiologically, and of glutamic-aspartic acid transaminase activity colorimetrically, in the tumours and in the tissues of several organs.

Vitamin B₆ concentration was much less in tumour tissue than in any normal tissues, except spleen, lung and sometimes testis. Treatment with testosterone significantly reduced the content of the tumours, but had no effect on their growth. The tumours had been previously shown to be sensitive to deoxypyridoxine (Absts. 459, Vol. 19; 1753, Vol. 20). Combination of deoxypyridoxine with, testosterone inhibited tumor growth at a dosage of deoxypyridoxine which, alone, was ineffective. The triple combination of 8-azaguanine, deoxypyridoxine and testosterone was more effective in inhibiting tumour growth than 8-azaguanine alone or any double combination. Transaminase activity was low in tumour tissue and was inhibited by deoxypyridoxine; inhibition of the enzyme in normal and tumour tissue was inversely proportional to the enzyme concentration.—V. R. Jackson.

1807

MARNAY, C. **Libération de l'acide pantothenique de diverses formes combinées distinguées par chromatographie sur papier et hydrolyses**

N.A. and R., April 1954

enzymatiques. [**Liberation of pantothenic acid in different combined forms differentiated by paper chromatography and by enzymic hydrolysis.**] *Bull. Soc. Chim. biol.*, 1953, **35**, 1171-1176. [Lab. Hyg., Fac. Pharm., Paris.]

Extracts were made of rat liver, heart and kidney by boiling, autolysis or enzyme action; paper chromatograms were made and compared with those for pure pantothenic acid, pantethine and co-enzyme A.

The presence of free pantothenic acid was demonstrated in the liver and kidneys. Autolysis of liver, heart and kidney tissue produced free pantothenic acid with the same chromatogram as the pure vitamin and the same effect on the growth of *Lactobacillus arabinosus*. For the last test the organisms were incubated with the appropriate zones cut from the chromatogram papers and growth was estimated electrophotometrically.

Co-enzyme A was released from tissues by hydrolysis with Lipmann's enzymes (Abst. 1840, Vol. 17) and was found to be present in large amounts in liver and kidney, but it was not affected by Mylase P which did, however, act upon another conjugate of the vitamin in these tissues. Another form, which was very mobile on the chromatogram, was not identified.

A conjugated form of pantothenic acid was found in heart tissue which was hydrolysed only slightly by Lipmann's enzymes and more by Mylase P than were the conjugated forms in liver and kidney. This finding tended to confirm the observation made by King *et al.* (Abst. 469, Vol. 19) of a form in heart tissue conjugated differently from co-enzyme A and resistant to alkali.

MOUCHETTE, R. Action de l'acide pantothenique sur la régénération de la peau de cobaye. [**Effect of pantothenic acid on skin regeneration in the guineapig.**] *C.R. Soc. Biol.*, 1953, **147**, 1306-1309. [Inst. Histol., Univ. Liège.]

Skin lesions were made on the hind paws of young male guineapigs by an application of carbon dioxide snow. Immediately afterwards and subsequently, daily, one paw of each animal was painted with 5 per cent. Na pantothenate solution and the other was left untreated. In a few animals neither paw was treated, and in others intraperitoneal injections of pantothenate replaced the skin painting. Normal animals were treated with pantothenate. Samples of skin

were taken and mitoses were counted. Painting with pantothenate caused a considerable increase in the number of mitoses in damaged skin; some increase was observed also in the untreated paws and entire skin of the same animals, and also in the skin of the normal animals treated with pantothenate. Injection of pantothenate caused increased mitoses in areas of skin regeneration.

GIUNCHI, G., FIDANZA, A., SCURO, L. A. and SORICE, F. Influenza della penicillina, diidro-streptomycina, cloramfenicolo ed aureomicina sull'accrescimento e sulla comparsa di anticorpi circolanti antieritrocitari in ratti alimentati con dieta priva di acido pantotenico. [**Effect of penicillin, dihydrostreptomycin, chloramphenicol and aureomycin on the growth and production of circulating haemolytic antibodies in rats given a diet without pantothenic acid.**] *Internat. Ztschr. Vitaminforsch.*, 1953, **25**, 1-7. [Ist. Clin. Med., Univ. Rome.] French, German and English summaries.

For the part of the paper concerning growth, see Abst. 451, Vol. 24.

The rats employed for the observations on growth were at the same time immunised by intraperitoneal injection of human red cells. The production of antibodies against human red cells was almost nil in the rats deprived of pantothenic acid; in the rats given antibiotics it was quite as good as in those given pantothenate, except for chloramphenicol, with which antibody production was somewhat less.—E. M. Hume.

1811

GIUNCHI, G., SCURO, L. A., SORICE, F. and FIDANZA, A. Acido pantotenico e produzione di anticorpi. [**Pantothenic acid and antibody production.**] *Riv. Ist. sieroterap. ital.*, 1953, **28**, 281-292. [Ist. Clin. Med., Univ. Rome.] English summary.

Of 59 rats weighing from 30 to 50 g., 25 were given a complete synthetic diet containing 100 mg. Ca pantothenate per kg. diet, and the remainder were given the diet without pantothenate. All the rats were immunised with human red cells, and 36 of them were immunised with a vaccine of *Salmonella typhi* or *Brucella melitensis*. From 10 to 25 days later the agglutinating titre of the blood was estimated. The result for red cell agglutinins was the same as is described in the preceding Abst. With the bacterial antigens, all the rats receiving pantothenate except 2 developed an agglutinating titre which was of varying strength; all except 3 of those deprived of pantothenic acid failed to do so.—E. M. Hume.

BIOTIN

1812

LITSKY, W., KATSH, S., TEPPER, B. S. and ALPERN, J. **Studies on the biotin requirement of the rat.** *Growth*, 1953, **17**, 81-86. [Dept. Bacteriol., Univ. Massachusetts, Amherst.]

Groups of weanling rats receiving a diet very low in biotin grew moderately and did not develop signs of biotin deficiency, whereas animals on a diet containing a considerable amount of biotin and 40 per cent. of dried egg white grew very little and developed severe signs of biotin deficiency within about 40 days. Addition of sulphaguandine to the low-biotin diet did not produce the signs of deficiency. It seemed that with a purified diet an intake of 7 μ g. biotin per 10 g. food was adequate for maintenance of young rats.

HAM, W. E. and SCOTT, K. W. **Intestinal synthesis of biotin in the rat. Effect of deficiencies of certain B vitamins and of sulfasuxadine and terramycin.** *J. Nutrition*, 1953, **51**, 423-433. [Dept. Animal Husb., State Coll. Washington, Pullman.]

Weanling female rats received for 25 days a basal synthetic diet containing vitamins B₁, B₆, A and D, riboflavin, nicotinic acid, Ca pantothenate, choline and menadione. During the following 12 to 14 days urine and faeces were collected and microbiological estimations were made of biotin. The basal diet was varied by altering the proportions of sucrose and starch, by additions of sulphasuxidine or terramycin or both, and of folic acid, and by omission of single vitamins. In one series of tests the rats received a stock diet with or without addition of antibiotics and folic acid.

In rats receiving the basal diet, synthesis of

biotin was demonstrated in the intestine. On the addition of 2 per cent. sulphasuxidine, total synthesis and daily excretion were reduced by 50 per cent., and the addition of folic acid did not affect the reduction. Deficiency of vitamin B₁ decreased the total amount of biotin excreted but not the amount per g. faeces and, since faecal material was reduced by 40 per cent. compared with a non-deprived group, it appeared that the decreased excretion was due to anorexia caused by the deficiency. Deficiency of riboflavin, nicotinic acid or Ca pantothenate caused a decrease in total excretion and in the amount per g. excreta, showing that lack of them had a direct effect on synthesis by the intestinal flora. Deficiency of vitamin B₆ had no effect. Replacement of sucrose by raw potato starch increased the amount of biotin synthesised, even in the presence of sulphasuxidine. Terramycin had an effect like that of sulphasuxidine, and both together almost completely inhibited intestinal synthesis of biotin.

V. R. Jackson.

1815

TERROINE, T. **Protection par l'acide ascorbique contre la carence en biotine chez le rat. [Protection by ascorbic acid against biotin deficiency in the rat.]** *C.R. Acad. Sci.*, 1953, **237**, 1030-1032.

Three groups of rats received the biotin-deficient diet described previously (Abst. 452, Vol. 24), alone or with addition of vitamins B₁ and B₆ and riboflavin, or of 1 or 5 g. ascorbic acid per kg. diet.

The group without any supplement and that with additional B vitamins developed signs typical of biotin deficiency, including alopecia, spectacled eyes and abnormal gait. In the groups having ascorbic acid, the signs of deficiency were reduced or suppressed, survival time was decreased and growth rate was improved.

The results tended to confirm previous observations by De Felice (Abst. 436, Vol. 23) of a favourable effect of biotin on the general health of guineapigs and on tissue ascorbic acid values.

p-AMINO BENZOIC ACID

1816

NURMIKKO, V. **Studies on the biosynthesis of p-aminobenzoic acid by symbiosis experiments.** *Acta chem. scand.*, 1953, **7**, 942-950. [Biochem. Inst., Helsinki.]

A strain of *Lactobacillus arabinosus* needing phenylalanine for growth and of *Streptococcus faecalis* R needing folic acid were incubated separately or together in the medium of Henderson and Snell (Abst. 1656, Vol. 18) slightly modified,

as previously described (Nurmikko, *Acta chem. scand.*, 1952, **6**, 1258). Growth was estimated by electrometric titration.

Neither organism alone grew in the medium when folic acid, phenylalanine, adenine, guanine, xanthine, uracil and p-aminobenzoic acid were all omitted, but they grew together if all were omitted except p-aminobenzoic acid. p-Aminobenzoic acid could be replaced by L-phenylalanine for growth of *L. arabinosus* and, since *S. faecalis* did not need

N.A. and R., April 1954

p-aminobenzoic acid, it was concluded that inhibition of symbiotic growth in a medium from which folic acid and phenylalanine had been omitted (see previous paper quoted above) was due to inability of *L. arabinosus* to synthesise *p*-aminobenzoic acid and folic acid in the absence of phenylalanine. The replacement of *p*-aminobenzoic acid by phenylalanine was inhibited by sulphanilamide and to some extent by benzoic acid. The inhibitory effect disappeared on addition of minute amounts of *p*-aminobenzoic acid.

In other symbiosis tests, *p*-aminobenzoic acid could be replaced by *p*-nitrophenylacetic, *p*-amino-phenylacetic, *p*-nitrobenzoic, *p*-iodobenzoic or *p*-aminohippuric acid. With the first two of these, *L. arabinosus* grew relatively more rapidly than *S. faecalis* R.

In the complete basal medium, shikimic acid could replace phenylalanine for *L. arabinosus*.

The mechanism of the conversion of phenylalanine to *p*-aminobenzoic acid is discussed.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

1817

HEINRICH, M. R., DEWEY, V. C. and KIDDER, G. W. **Ion-exchange chromatography of pteroylglutamic acid and aminopterin.** *J. Amer. Chem. Soc.*, 1953, **75**, 5425-5426. [Biol. Lab., Amherst Coll., Mass.]

An ion exchange chromatogram of aminopterin showed a small peak in addition to that of aminopterin itself. The peak was characteristic of pteroylglutamic acid, of which it was possible to demonstrate the characteristic properties by collecting the impurity from a number of samples.

R. Marshall.

1818

ZAKRZEWSKI, S. F. and NICHOL, C. A. **The separation and determination of pteroylglutamic acid and related compounds.** *J. Biol. Chem.*, 1953, **205**, 361-368. [Dept. Pharmacol., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

Some antagonists of pteroylglutamic acid have been found to promote growth of *Tetrahymena* and *Streptococcus faecalis*, so a sample of aminopterin was examined by bio-autographic and chromatographic technique. With an aqueous solvent phase buffered to about pH 6.3, pteroylglutamic acid was isolated from aminopterin in considerable amount. Fluorimetric and microbiological estimations showed that from 22 to 24 per cent. was actually present. Such an amount of the growth-promoting substance would obviously complicate the study of resistance to the antagonist.

1819

WOODRUFF, C. W., CLARK, S. L. (Jr.) and BRIDGEFORTH, E. B. **Folic acid deficiency in the guinea pig.** *J. Nutrition*, 1953, **51**, 23-34. [Dept. Paediat., Dept. Med., Vanderbilt Sch. Med., Nashville, Tenn.]

Guineapigs were given purified diets with vitamin and mineral supplements, or a commercial guineapig diet, from about 6 weeks of age for a period of 6 weeks. Blood studies were made with capillary blood from the ear or with heart blood. Growth was slower on the purified diets

than on the commercial mixture, and scurvy occurred if no vitamin C was given. In animals having no folic acid the growth rate was depressed but blood changes did not occur unless 1 per cent. sulphasuxidine was included; leucopenia, anaemia and immaturity of red cell precursors in the bone marrow then occurred, but were prevented by inclusion of 3.0 mg. folic acid per kg. diet. If *p*-aminobenzoic acid was omitted no blood changes occurred if folic acid was included. If both were omitted growth failed and blood changes were as severe as when sulphasuxidine was included in a diet without folic acid. Blood changes occurred with diets containing *p*-aminobenzoic acid and sulphasuxidine. The probable role of the intestinal flora in the synthesis of folic acid in the guineapig is discussed.—A. M. Copping.

1820

MALDONADO, J. F. and ASENJO, C. F. **The role of pteroylglutamic acid and vitamin B₁₂ on the development of *Nippostrongylus muris* in the rat.** *Exp. Parasitol.*, 1953, **2**, 374-379. [Sch. Med., Univ. Puerto Rico, San Juan.]

Weanling white rats were given a purified basal diet with or without a supplement of folic acid or vitamin B₁₂ or both, and another group had a normal commercial diet. After 3 weeks the rats were inoculated subcutaneously with infective larvae of *Nippostrongylus muris*. Nine days later they were killed, the adult worms were recovered from the intestine, and the larvae remaining in the lungs were counted. The numbers recovered from all the groups were about the same, and under the conditions of the study there was no evidence that folic acid or vitamin B₁₂ affected the development of the parasite.—A. M. Copping.

1821

RASK-NIELSEN, R. and BENNETT, E. **Investigations into the effect of thymonucleic acid fed to folic acid deficient chicks bearing Rous sarcomas.** *Acta pathol. microbiol. scand.*, 1953, **32**, 367-374. [Fibiger Lab., Inst. Pathol. Anat., Univ. Copenhagen.]

Chicks fed from hatching on a diet containing no folic acid, alone or with a supplement of folic acid or of thymonucleic acid and adenine, were inoculated with Rous sarcoma virus at the age of 6 days. Survival time, bodyweight and size of tumours were recorded.

In a first experiment the supplement of thymonucleic acid and adenine appeared to favour growth, but the result was not confirmed in a second test with a larger number of chicks. The number and size of the tumours in chicks having thymonucleic acid and adenine was less than in those having folic acid. In the second test there was no significant difference in susceptibility to tumours between the unsupplemented chicks and those having thymonucleic acid and adenine. It therefore remained doubtful whether thymonucleic acid and adenine could compensate for folic acid deficiency in the diet of chicks or not. A preliminary note with microbiological tests showed that chick pancreas could depolymerise thymonucleic acid, and that adenine was absorbed and incorporated into nucleic acids.—A. M. Copping.

1822

JACOBSON, W. **A folic acid derivative functioning during cell division.** *J. Physiol.*, 1953, **122**, 40P-41P. [Strangeways Res. Lab., Cambridge.]

1823

NIMMO-SMITH, R. H. and BROWN, D. J. **Some effects of 2-deaminopteroylglutamic acid upon bacterial growth.** *J. Gen. Microbiol.*, 1953, **9**, 536-544. [Microbiol. Unit, Dept. Biochem., Oxford.]

The capacity of 4 analogues of pteric acid and of 2-deaminopteroylglutamic acid to inhibit growth of *Streptococcus faecalis* R in presence of pteric acid or to stimulate its growth in absence of pteric acid was tested in a medium with or without pteric acid as source of folic acid. In some tests

ptericoic acid was replaced by pteroylglutamic acid, leucovorin or rhizopterin. Growth was estimated colorimetrically.

None of the compounds tested stimulated growth alone or in the presence of suboptimum amounts of ptericoic acid. With 2-deaminopteroylglutamic acid only, moderate inhibition of growth occurred in presence of ptericoic acid; the relation between ptericoic acid and its analogue was not exactly competitive, since the effect of the inhibitor increased greatly as the concentrations of both were increased. Growth supported by rhizopterin or leucovorin was less readily affected and inhibition decreased with increasing concentrations. With pteroylglutamic acid as source of folic acid the relation with the inhibitor appeared to be competitive. In a medium in which thymine and purine replaced folic acid, 2-deaminopteroylglutamic acid had no effect on growth.

In similar tests with *Lactobacillus casei*, growth was not supported by ptericoic acid or rhizopterin. Growth supported by pteroylglutamic acid was inhibited by 2-deaminopteroylglutamic acid, there being some evidence that the relation was competitive. Growth supported by leucovorin was more resistant to inhibition. Growth supported by thymine and purine was stimulated to a maximum by pteroylglutamic or 2-deaminopteroylglutamic acid. Explanations of the effect are discussed.

There was no effect of 2-deaminopteroylglutamic acid on the growth of organisms which did not need folic acid, including *Bacterium coli*, *L. arabinosus*, *L. plantarum* and *Schizosaccharomyces octosporus*.—V. R. Jackson.

BEARSE, G. E., SAXENA, H. C., McCLARY, C. F., BLAYLOCK, L. G. and BERG, L. R. **Deficiency of folic acid in rations containing natural feed-stuffs.** *Poultry Sci.*, 1953, **32**, 889. *Proc. [W. Washington Exp. Stat., State Coll. Washington, Puyallup.]*

VITAMIN B₁₂

1825

FORD, J. E. **The microbiological assay of 'vitamin B₁₂'. The specificity of the requirement of *Ochromonas malhamensis* for cyanocobalamin.** *Brit. J. Nutrition*, 1953, **7**, 299-306. [Nat. Inst. Res. Dairying, Univ. Reading.]

The specific requirement of the protozoön *Ochromonas malhamensis* for vitamin B₁₂ was investigated with a modified synthetic medium similar to that developed by Hutner, Provasoli and Filfus (*Ann. N.Y. Acad. Sci.*, 1953, **55**, 852). Tests were made with cyanocobalamin, factors A, B and C (see Abst. 1839, Vol. 24), and pseudovitamin

B₁₂ for the growth of *Bacterium coli*, *Lactobacillus leichmannii*, *Euglena gracilis* and *Ochromonas malhamensis*. Compounds related to cyanocobalamin appeared incapable of replacing the vitamin for *Ochromonas*, which responded in a more specific manner than the other micro-organisms. Comparison with *Bact. coli* showed that *Ochromonas* gave the more satisfactory estimate of the true vitamin B₁₂ content of crude extracts from natural products, including those containing related substances which showed activity for *Bact. coli*. *Ochromonas* is therefore recommended as a test organism for vitamin B₁₂.—A. M. Copping.

POLONOVSKI, M. and LÉVY, G. Microdosage microbiologique du facteur citrovorum. [**Microbiological micro-estimation of citrovorum factor.**] *Bull. Soc. Chim. biol.*, 1953, **35**, 1167-1169. [Serv. Biochim. Méd., Fac. Méd., Paris.]

Small tubes of capacity of 6 ml., containing 1 ml. of a synthetic medium which is described and 1 ml. of the solution to be examined, were sterilised and inoculated with *Leuconostoc citrovorum*. Nephelometric estimation was made of citrovorum factor after incubation for 20 hr. at 37° C. by comparison with standard curves obtained with solutions containing from 0.05 to 1.0 mμg. synthetic citrovorum factor per ml. The values were comparable with those obtained when 10 ml. medium were used. Titrimetric estimations could be made after incubation for 72 hr.

The observations of Gaines *et al.* (Abst. 3485, Vol. 21) that cortisone or its acetate possessed folic or folinic acid activity could not be confirmed. V. R. Jackson.

1827

McLAUGHLAN, J. M., CLARK, J. A. and CAMPBELL, J. A. The effect of cyanide on the apparent vitamin B₁₂ content of liver extracts in *E. coli* plate assays. *Arch. Biochem. Biophys.*, 1953, **46**, 244-246. [Food and Drug Lab., Dept. Nat. Health, Ottawa.]

When the vitamin B₁₂ potency of 6 different liver extracts was estimated by the pad-plate technique with *Bacterium coli* the results were about 50 per cent. higher than those obtained by estimation in tubes with *Lactobacillus leichmannii*. The discrepancy was eliminated if the liver extracts were treated with cyanide during preparation for estimation by the plate method; the values were then lower and in harmony with those of the tube method.—A. M. Copping.

1828

DENTON, C. A. and KELLOGG, W. L. The vitamin B₁₂ activity of eggs and some materials as affected by extraction in the presence of sodium cyanide or sodium bisulfite. *Arch. Biochem. Biophys.*, 1953, **46**, 105-109. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Addition of cyanide or bisulphite to buffer solutions in making extracts of egg yolk for microbiological estimation of vitamin B₁₂ produced a great increase in the apparent vitamin B₁₂ activity. The presence of cyanide or bisulphite allowed satisfactory recovery of vitamin B₁₂ added to extraction mixtures. The two substances were effective in releasing and protecting vitamin B₁₂ from eggs, day-old chicks and caecal contents

from hens, but did not influence the amount from hen's liver, fishmeal, meatmeal or cow dung.

1829

HEATHCOTE, J. G. The analysis of analogues. A general technique applied to the estimation of cyanocobalamin and hydroxycobalamin in mixtures of the vitamins. *Chem. and Indust.*, 1953, No. 45, 1203. [Distillers Co. (Biochemicals), Ltd., Speke, Liverpool.]

Absorption curves of vitamins B₁₂ and B_{12b} show maxima at 361 and 351 mμ. The measurement of absorption at 356 mμ. for a mixture gives the total of both vitamins in the solution. Addition of benzyl alcohol to an aqueous solution of the vitamins and measurement of absorption at 356 mμ. for each phase gave a coefficient for apparent vitamin distribution between the phases. This coefficient was a function of the composition of the sample and could be compared with results obtained with artificial mixtures as standards.

NICHOL, C. A. The effect of ascorbic acid on the enzymatic formation of the citrovorum factor. *J. Biol. Chem.*, 1953, **204**, 469-475. [Dept. Pharmacol., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

Homogenates of liver from chicks which had been on a diet devoid of folic acid, when incubated anaerobically in the presence of ascorbate, were capable of converting 25 per cent. of added pteroylglutamic acid to citrovorum factor. Ascorbic acid could be replaced by glucoascorbic or isoascorbic acid but not by cysteine or glutathione. Ascorbic acid suppressed the enzymic destruction of natural and synthetic citrovorum factor which occurred under aerobic conditions, and also facilitated its active formation.

SAHASHI, Y., IWAMOTO, K. and HAYASHI, J. **Effect of vitamin B₁₂ on metabolism. 1.** *J. Biochem., Tokyo*, 1953, **40**, 245-249. [Biochem. Lab., Fac. Agric., Univ. Tokyo.]

Vitamins B₁ and B₁₂ were estimated in the blood of 2 young heifers before and after work on a treadmill. The exercise caused a decrease of both vitamins in the blood and of the red cell count. Injection of vitamin B₁ alone or with vitamin B₁₂ before exercise protected the animals against the decrease in the blood values for the 2 vitamins. The possible role of vitamin B₁₂ in energy metabolism is discussed in relation to the vitamin B₁ and pyruvate system.—A. M. Copping.

1834

DOCTOR, V. M., WELCH, B. E., PERRETT, R. W., BROWN, C. L., GABAY, S. and COUCH, J. R. **Metabolic interrelationship between folic acid, vitamin B₁₂, and the citrovorum factor.** *Proc. Soc. Exp. Biol. Med.*, 1953, **84**, 29-32. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Day-old chicks in groups of 12 were given a basal diet low in vitamin B₁₂ and folic acid, alone or with supplements per kg. diet of 2, 100 or 400 mg. folic acid, or 30 or 500 µg. vitamin B₁₂. After 4 weeks tests were made of the ability of the liver to synthesise citrovorum factor *in vitro* from added folic acid. Presence of vitamin B₁₂ or folic acid in the diet increased the amount of citrovorum factor synthesised *in vitro*, roughly in proportion to the amounts given. Addition of vitamin B₁₂ and sodium formate *in vitro* to liver preparations from deficient birds had very little effect. The vitamin B₁₂ content of the liver was increased by increasing amounts of vitamin B₁₂ and folic acid in the diet. The possibility is discussed that vitamin B₁₂ and folic acid have specific effects on the enzyme system converting folic acid into citrovorum factor.—A. M. Copping.

1835

DREYER, H. Untersuchungen über den Einfluss von Vitamin B₁₂ und APF auf den Eiweissstoffwechsel. [Effect of vitamin B₁₂ and APF on protein metabolism.] *Arch. Tierernährung*, 1953, **3**, 240-258. [Inst. Tierernährung, Forschungsanst. Landwirtsch., Völkenrode, Brunswick.]

The initial investigation of the effect of vitamin B₁₂ and animal-protein factor on protein metabolism was made on 52 pigs given a fattening ration with or without an adequate supplement of fishmeal. In the ration of low fishmeal content, addition of crystalline vitamin B₁₂ had no beneficial effect, but crude animal-protein factor increased weight gain and feed intake. Metabolism studies

were made with pigs and with rats on diets containing only vegetable protein. Crystalline vitamin B₁₂ had no effect on N retention in any of the tests. In one experiment with young growing pigs animal-protein factor produced some increase in N retention. It had no effect on N retention by rats. A supplement of methionine increased N retention by rats from a diet containing protein from soya bean.

In a final series of experiments, growth response was measured in young rats given protein from soya bean, field bean or pea with a supplement of methionine, cystine, vitamin B₁₂ or animal-protein factor. All the supplements except cystine improved the growth response, and the combination of cystine and animal-protein factor was more effective than animal-protein factor alone. Methionine was the most effective supplement, and it is suggested that the effect of vitamin B₁₂ and animal-protein factor is related to their function in transmethylation systems.—A. M. Copping.

KRUH, J., DREYFUS, J. C. and SCHAPIRA, G. Recherches sur la biochimie de l'hémoglobine à l'aide de fer radioactif. 5. Biosynthèse des hémoglobines *in vitro*. [Studies on the biochemistry of haemoglobin with radio-active iron. 5. Biosynthesis of haemoglobins *in vitro*.] *Bull. Soc. Chim. biol.*, 1953, **35**, 1181-1188. [Lab. Recherches Biochim. Méd., Hôp. Enfants Malades.]

Red blood cells from rabbits made anaemic by bleeding or injection of phenylhydrazine incorporated radio-active Fe into the Hb *in vitro* when suspended in Ringer solution containing antibiotics. By alkaline denaturation or adsorption on alumina the Hb could be separated into 2 fractions, differing in the speed at which they incorporated Fe. The relation between the specific activities acquired by these forms was the opposite of that found in tests *in vivo* (Kruh *et al.*, *Bull. Soc. Chim. biol.*, 1952, **34**, 773; 778; Schapira *et al.*, *ibid.*, 1951, **33**, 812; 822, and others), but became similar to that observed *in vivo* on addition to the medium of bone marrow, liver extract, vitamin B₁₂ or folic acid.—V. R. Jackson.

1837

POLOSA, P., DE FRANCISCIS, G. and NEGRO, L. Variazioni delle resistenze globulari dopo trattamento con acido folico e vitamina B₁₂ nei cani salassati. [Variations in the resistance of the red cells in exsanguinated dogs after treatment with folic acid and vitamin B₁₂.] *Arch. Fisiol.*, 1952-53, **53**, 394-402. [Ist. Patol., Univ. Catania.]

Blood was withdrawn from 5 dogs to the extent of 1/70th of the bodyweight. Two were treated

for 4 days afterwards with 30 mg. daily of folic acid, 2 for 6 days with 15 μ g. daily of vitamin B₁₂, and one had no treatment. The resistance of the red cells to haemolysis in hypotonic saline was measured by the method of Simmel before and after blood-letting. In the untreated dog, the mean resistance of the red cells increased after blood-letting. In the treated dogs, no consistent difference from the untreated was recorded.

COATES, M. E. **The mode of action of antibiotics in animal nutrition.** *Chem. and Indust.*, 1953, No. 50, 1333-1335. [Nat. Inst. Res. Dairying, Univ. Reading.]

1839

COATES, M. E., FORD, J. E., HARRISON, G. F., KON, S. K. and PORTER, J. W. G. **Vitamin B₁₂-like compounds. 1. Vitamin B₁₂ activity for chicks and for different micro-organisms of gut contents and faeces.**

FORD, J. E. and PORTER, J. W. G. **2. Some properties and compounds isolated from bovine gut contents and faeces.** *Brit. J. Nutrition*, 1953, 7, 319-326; 326-337. [Nat. Inst. Res. Dairying, Univ. Reading.]

1. The vitamin B₁₂ activity of rumen contents and of faeces from calves was measured biologically with chicks and microbiologically with *Lactobacillus leichmannii*, *Bacterium coli* and *Euglena gracilis*. The values obtained with *L. leichmannii* were lower than those with *Bact. coli* or *Euglena gracilis* and the values in all microbiological tests were increased when the faeces and gut contents were treated with cyanide in the process of extraction. With chicks the results were lower than those obtained with the micro-organisms.

Incubation of calf faeces produced an increase in the vitamin B₁₂ activity available for chicks, but not in that for micro-organisms. The discrepant results with the different micro-organisms are discussed, and it is suggested that the gut contents and faeces contained vitamin-B₁₂-like compounds with different activities for chicks and for the several organisms.

2. Extracts of the gut contents and faeces of calves made in the presence of cyanide were examined chromatographically, and three factors other than cyanocobalamin were identified and named A, B and C. Factor A was obtained from faeces in crystalline form. Factor B was isolated but not crystallised and only minute amounts of factor C were obtained. Spectrographic examination showed that factor A closely resembled cyanocobalamin and that the absorption spectrum of factor B showed different peaks. Ionophoresis showed that the apparently homologous crystals

of factor A contained small amounts of the other factors.

The vitamin B₁₂ activities of the three factors varied not only according to the organism used but also with the method of test, i.e., whether, in the case of *Bact. coli*, plate or tube culture was used. Factor A was almost as active as cyanocobalamin for *Bact. coli* in plate tests and for *Euglena gracilis*, but relatively inactive in tube tests with *Bact. coli*, and for *L. leichmannii*. Factors B and C were active for *Bact. coli* in plate tests but much less active in tube tests, and for *L. leichmannii* and *Euglena gracilis*.

When fresh calf faeces were incubated, their content of cyanocobalamin increased and that of factor A decreased. In growth studies with *Bact. coli*, factor A and cyanocobalamin appeared to be incorporated unchanged into the cells but factor B was transformed into factor C.—A. M. Copping.

1840

GREGORY, M. E. and HOLDSWORTH, E. S. **The combination of some vitamin B₁₂-like compounds with sow's milk whey and 'intrinsic factor' concentrates.** *Biochem. J.*, 1953, 55, 830-834. [Nat. Inst. Res. Dairying, Univ. Reading.]

In continuation of previous studies on a substance in sow's whey which combined with vitamin B₁₂ (Title 394, Vol. 23), the reaction of other substances with vitamin B₁₂ activity was investigated (see preceding Abst.). Factors A and B and pseudovitamin B₁₂ were purified by repeated ionophoresis and their growth-promoting activity for *Bacterium coli* was estimated as a percentage of that of pure vitamin B₁₂; for factor A the percentage was 66, for factor B 22 and for pseudovitamin B₁₂ 8. The amounts of these 3 factors which were able to combine with a concentrate from sow's whey and with a preparation of intrinsic factor from pig's stomach were proportional to their vitamin B₁₂ activities.—A. M. Copping.

1841

SAHASHI, Y., IWAMOTO, K., MIKATA, M., NAKAYAMA, A., SAKAI, H., TAKAHASHI, J., HAYASHI, J., SENO, N., AKATSUKA, T., MIKI, T., HARASHIMA, K. and MATSUMOTO, R. **Biosynthesis of vitamin B₁₂ in various organisms. 1. J.** *Biochem., Tokyo*, 1953, 40, 227-244. [Biochem. Lab., Fac. Agric., Univ. Tokyo.]

The failure of vitamin B₁₂ synthesis by actinomycetes in the rumen was investigated as a cause of *kuwazu*, *kuiyami* and *kiriyo* disease in cattle. No actinomycetes capable of synthesising vitamin B₁₂ were identified in the faeces of animals suffering from these conditions. Intramuscular injection of vitamin B₁₂ cured the diseases. The possibility is suggested that fluorine may inhibit the synthesis

of vitamin B₁₂ by the rumen flora and thus disturb the whole metabolic system.

In experiments with rats on diets lacking vitamin B₁₂ no evidence of deficiency was obtained and no anaemia occurred. See also Abst. 4157, Vol. 23.

In chicks, actinomycetes actively synthesising vitamin B₁₂ were found in the droppings, but none was isolated from any part of the alimentary tract and none from fresh droppings. Actinomycetes administered to chicks did not prevent the results of lack of vitamin B₁₂.

Examination of silkworm ova, larvae, pupae and moths showed the presence of vitamin B₁₂ at all stages of development, but there was no vitamin B₁₂ in the mulberry leaves forming the sole diet.

A. M. Copping.

1842

PETERSON, G. E., DICK, E. C. and JOHANSSON, K. R. **Influence of dietary aureomycin and carbohydrate on growth, intestinal microflora and vitamin B₁₂ synthesis of the rat.** *J. Nutrition*, 1953, **51**, 171-189. [Dept. Bacteriol., Univ. Minnesota, Minneapolis.]

Purified basal diets with sucrose or dextrin as carbohydrate, and soya bean protein, and lacking vitamin B₁₂, were given to weanling female rats for 7 days, after which the rats on each diet were divided into 4 groups having 25 µg. vitamin B₁₂ per kg. diet, or 100 p.p.m. crystalline aureomycin hydrochloride or both, or no supplement. Growth was followed for 42 days and the microflora of pooled faeces from each group was examined 16, 40, 112 and 192 hr. after the experimental diets were first given, and of the ileal and caecal contents after 42 days.

The vitamin B₁₂ content of the kidneys and liver at the end of the experiment was greater in animals having vitamin B₁₂ but not in those having aureomycin. The concentration of vitamin B₁₂ in the contents of the caecum, ileum and colon was increased in rats having aureomycin. There was a positive correlation between the growth response and the concentration of free vitamin B₁₂ in the intestinal contents. Inclusion of aureomycin in the diet increased the growth of rats whether vitamin B₁₂ was given or not.

The nature of the intestinal flora was affected by the carbohydrate constituent of the diet. Aureomycin in the sucrose diet gave increased counts of *Proteus*, enterococci and aureomycin-resistant bacteria, decreased counts of *Clostridium perfringens* and lactobacilli, and no change in the numbers of coliform bacteria. With dextrin the coliform bacilli increased, *C. perfringens* was not affected and lactobacilli were only slightly less numerous. The effect of aureomycin was seen within 40 hr.

The bearing of the results on the problems of

intestinal synthesis and absorption of vitamin B₁₂ is discussed.—A. M. Copping.

1843

BARBER, R. S., BRAUDE, R., KON, S. K. and MITCHELL, K. G. **Antibiotics in the diet of the fattening pig.** *Brit. J. Nutrition*, 1953, **7**, 306-319. [Nat. Inst. Res. Dairying, Univ. Reading.]

Aureomycin, penicillin and aureomycin residues were studied in 4 experiments. In the first, pigs received a diet containing 10 per cent. fishmeal and the supplements caused only a slight increase in growth rate. In the second test, antibiotic supplements added to diets containing only vegetable proteins raised growth and feed utilisation to equal those of pigs having 10 per cent. animal protein in the diet. The third experiment was complicated by an undiagnosed illness, from which recovery took place; it affected all the animals except those receiving penicillin, which made the best weight gains whether their diets contained animal protein or solely vegetable protein. In the fourth experiment, where the Lehmann system of giving bulky fodder was used, the rate of gain was improved by the antibiotic supplements and the best results were obtained when the diets contained 2.5 per cent. fishmeal.

Some of the pigs in the last 3 experiments developed coughs which yielded to sulphonamides, but were not affected by the antibiotics in the diets. Urine, faeces and intestinal contents were examined and, though the presence of antibiotic could be demonstrated throughout the intestinal tract, no demonstrable change in gut flora occurred. The antibiotics were effective in the presence and absence of vitamin B₁₂ in the diet, and examination of the stomach, duodenum, caecum and colon of pigs on different diets showed no marked difference in vitamin B₁₂ content. The vitamin B₁₂ stores in the liver were greater in pigs receiving the vitamin in their diets. The vitamin A stores in the liver were not affected by vitamin B₁₂ or antibiotics in the diets.

The carcasses were subjected to detailed examination and the results showed that consumption of antibiotics had no effect on the quality of the bacon.—A. M. Copping.

1844

MIRONE, L. and WADE, E. M. **Vitamin B₁₂ and cobalt chloride in growth and reproduction of four strains of mice.** *Amer. J. Physiol.*, 1953, **175**, 11-12. [Dept. Nutrit., Univ. Georgia, Athens.]

Addition of 50 µg. vitamin B₁₂ or of 58 mg. cobalt per kg. to a purified diet containing 23 per cent. casein did not have any significant effect on growth or reproduction in mice of the C₃H, C₅₇,

N.A. and R., April 1954

CF, or dba strains. Experiments were made with 80 female mice which received the purified diet from weaning and with 52 which had stock diet until the time of mating. The reproductive performance was better in the latter group, and was not improved by the supplement of vitamin B₁₂.

1845

LASSITER, C. A., WARD, G. M., HUFFMAN, C. F., DUNCAN, C. W. and WEBSTER, H. D. **CrySTALLINE vitamin B₁₂ requirement of the young dairy calf.** *J. Dairy Sci.*, 1953, **36**, 997-1005. [Dept. Dairy, Michigan Agric. Exp. Stat., East Lansing.]

In studies with 23 calves which from 48 hr. after birth were given a synthetic milk diet with alpha protein, a soya bean preparation, as the sole protein, growth ceased with loss of appetite and general poor condition if no vitamin B₁₂ was given. Average daily weight gains were measured in calves without, and with 10, 20 or 40 µg. vitamin B₁₂ per kg. dry matter of the diet. A maximum response was obtained with 40 µg. and a moderate response with 20 µg. Some batches of alpha protein proved unsatisfactory for calf feeding, and the effect was attributed to presence of a toxic factor. The observation was confirmed in tests with rats, which also showed poor growth on diets containing the unsatisfactory alpha protein.

CARLSON, C. W., GUENTHNER, E., KOHLMAYER, W. and OLSON, O. E. **Some effects of selenium, arsenicals, and vitamin B₁₂ on chick growth.** *Poultry Sci.*, 1953, **32**, 891. *Proc.* [S. Dakota Agric. Exp. Stat., College Station.]

1847

GERLICH, N. and REMY, R. **Aftiperniciös wirk-same Stoffe bei der Bleianämie. [Substances with anti-pernicious-anaemia activity in lead anaemia.]** *Arch. exp. Pathol. Pharmacol.*, 1953, **220**, 351-357. [Städt. Krankenhaus, Bielefeld.]

Groups of 9 male rabbits weighing from 2 to 3 kg. were given lead acetate intravenously for 3 consecutive days, and certain groups received in addition liver extract or vitamin B₁₂. With Pb alone the rabbits developed anaemia which reached its maximum on the fifth day. When the combined injections were given, the rate of development and severity of the anaemia were significantly reduced. The effect of the liver extract was equal to that of a dose of vitamin B₁₂ 3 or 4 times greater than its ascertained vitamin B₁₂ content. Folic acid similarly administered had much less effect than liver extract or vitamin B₁₂. Cobalt given with the lead, in amounts equal to those in the doses of vitamin B₁₂ found to be protective, had

no effect on the anaemia but, on the third day after a large dose, 0.08 mg. per kg. bodyweight, both the red cells and the Hb began to rise, and by the fifth day had risen from a minimum value of 2.4 to 4.0 million and to 70 from 45 per cent., respectively.—L. Wills.

1848

LABÒ, G., GIANNI, A. M. and DESSI, P. **Azione della vitamina B₁₂ in corso di avvelenamento con formiato di allile. [Effect of vitamin B₁₂ on poisoning with allyl formate.]** *Acta vitaminol.*, 1953, **7**, 197-199. [Ist. Clin. Med., Univ. Bologna.] English, French, German and Spanish summaries.

Two groups of 9 rats weighing about 85 g. were maintained on a complete diet, and were given on alternate days 0.014 ml. per kg. bodyweight of allyl formate in 10 per cent. oily solution. One group received in addition daily 150 µg. vitamin B₁₂ per kg. bodyweight. Three rats from each group were killed after 18, 40 and 44 days, and lipids were estimated in the liver. In the liver the histological picture of injury was much less severe in the rats given vitamin B₁₂, and the concentration of fat was not much more than half that in the untreated rats.—E. M. Hume.

1849

SREENIVASAMURTHY, V., NAMUDRIPAD, V. K. N. and IYA, K. K. **Further studies on the vitamin B₁₂ activity of milk.** *Indian J. Dairy Sci.*, 1953, **6**, 105-109. [Indian Dairy Res. Inst., Bangalore.]

Vitamin B₁₂ in its heat-stable form of cyanocobalamin and its labile form of hydroxocobalamin was estimated with *Lactobacillus lactis* Dorner in milk from cows of 4 breeds and in human milk. In human milk the activity was mainly present as cyanocobalamin and ranged from 0.055 to 0.16 µg. per ml. The values for cow's and buffalo's milk were higher and ranged from 2.7 to 9.0 µg. per ml., with much hydroxocobalamin included in the total. The milk from crossbred cows was generally richer in vitamin B₁₂ than milk from Gir, Sindhi or Tharparkar breeds.—A. M. Copping.

1850

SJÖSTRÖM, A. G. M., NEUJAHN, H. Y. and LUNDIN, H. **Vitamin B₁₂, folic acid and folinic acid factors in digested municipal sludge.** *Acta chem. scand.*, 1953, **7**, 1036-1040. [Royal Inst. Technol., Stockholm.]

Sludge from each of three sewage plants was found to contain growth factors for *Lactobacillus lactis* Dorner, *Leuconostoc citrovorum* and *Streptococcus faecalis*. The nature of the substances was investigated by chromatography or ionophoresis in conjunction with bio-autographic methods. Large

amounts of vitamin B₁₂ activity were present as hydroxocobalamin, factors A, B and C and pseudo-vitamin B₁₂. The amount of vitamin B₁₂ activity increased during anaerobic digestion of the sludge. Deoxyribosides and factors of the folic acid

group, including folinic acid, also were identified in fresh and in digested sludge, but no evidence was obtained of their production during the digestion process.—A. M. Copping.

VITAMIN C (ASCORBIC ACID)

1852

SCHMALL, M., PIFER, C. W. and WOLLISH, E. G. **Determination of ascorbic acid by a new colorimetric reaction.** *Anal. Chem.*, 1953, 25, 1486-1490. [Products Control Lab., Hoffmann-La Roche, Inc., Nutley, N.J.]

The method is based on the fact that ascorbic acid reacts with diazotised 4-methoxy-2-nitro-aniline in acid solution in such a way that when the solution is made alkaline a deep blue colour is obtained with maximum absorption at 570 mμ. The reaction was highly specific for ascorbic acid, depending on its enediol grouping and not directly on its reducing power. Dehydroascorbic and 2:3-diketogulonic acids and the vitamins normally present in multivitamin preparations did not interfere with the estimation. The method was rapid, simple and suitable for routine work, and in accuracy compared favourably with conventional procedures.—W. Godden.

separation on a paper chromatogram. *Biochem. J.*, 1953, 55, 821-823. [Low Temperature Res. Stat., Univ. Cambridge.]

L-Ascorbic acid and allied compounds were separated on a paper chromatogram by the use of 2 solvents, *n*-butanol saturated with water and oxalic acid, and phenol similarly saturated. The second solvent gave a clear-cut separation of L-ascorbic acid and D-araboascorbic acid. Details are given for the estimation of enediols from plant and animal tissues. Recovery of L-ascorbic acid and D-araboascorbic acid added to rat's urine or extracts of cress seedlings was 85 per cent.

HEIMANN, W., STROHECKER, R. and MATT, F. Zur Bestimmung der Ascorbinsäure auf papierchromatographischem Weg. [Estimation of ascorbic acid by paper chromatography.] *Ztschr. Lebensmittel - Untersuch. Forsch.*, 1953, 97, 263-270. [Inst. Lebensmittelchem., Tech. Hochsch., Karlsruhe.]

With the upper layer of a mixture of butanol, acetic acid and water as solvent, and molybdate solution as indicator, it was possible by ascending paper chromatography to separate ascorbic acid from the numerous substances which interfere in the ordinary estimation. An exact separation of isoascorbic acid from ascorbic acid, in the period of from 5 to 6 hr. adopted, was not possible owing to the similarity of their *R_F* values. The method could be used for quantitative estimations.

W. Godden.

1856

GUGGENHEIM, K., LEIBOWITZ, J. and RAKOVER, D. **Comparative observations on the chemical properties and biological activities of L-ascorbic and D-isoascorbic acids.** *Biochem. J.*, 1953, 55, 388-392. [Lab. Nutrit., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Ascorbic and isoascorbic acids were equally effective in detoxifying potassium cyanide, phenol and tetanus toxin and in increasing the urinary excretion of citrovorum factor by rats after injection of folic acid. They also showed similar abilities to combine with potassium cyanide and phenol in aqueous solution. It is concluded that, since the antiscorbutic activity of isoascorbic acid is negligible, that of ascorbic acid cannot be explained on the basis of its detoxifying activity.

1854

CHEN, Y. T., ISHERWOOD, F. A. and MAPSON, L. W. **Quantitative estimation of ascorbic acid and related substances in biological extracts by**

Part of the paper is a more detailed account of work already published (Abst. 2885, Vol. 16). The rise in urinary excretion of vitamin C in rats receiving chloretone daily was not affected by a high intake of detoxicating agents such as glycine or by removal of the pancreas or adrenal glands. Of the dehydrogenases studied in brain and liver tissues only those which dehydrogenated pyruvate and lactate were inhibited by previous administration of chloretone. Injection of enzyme inhibitors such as Na malonate, iodoacetate or fluoride did not affect the urinary excretion of vitamin C in normal rats or those receiving chloretone. The tissue reserves of vitamin C in normal rats was appreciably reduced by deficiency of vitamin B₁ or riboflavin, but vitamin C depletion had no effect on the vitamin B₁ content of the tissues. The urinary excretion of both citric acid and vitamin C fell to zero in vitamin-B₁-deficient rats, and was not raised by administration of chloretone. Administration of vitamin B₁ alone caused a rise in the citric acid excretion, but administration of both chloretone and vitamin B₁ was necessary to bring about a rise in urinary vitamin C.

NIKOLAEV, R. P., POVOLOTSKAYA, K. L. and VODOLAZSKAYA, N. A. Biologicheskaya tsennost razlichnykh kontsentratsionnykh preparatov vitamina C. [The biological value of different concentrates and preparations of vitamin C.] *Biokhimiya*, 1953, **18**, 169-174. [Vsesoyuz. Nauch.-Issled. Vitamin. Inst., Moscow.]

Experiments on guineapigs showed that vitamin C from natural sources such as rose hips was more effective in preventing scurvy and haemorrhage than pure synthetic vitamin C alone, but when vitamin P or natural products containing vitamin P or substances with vitamin P activity were given with synthetic vitamin C the results obtained were almost identical. Concentrates made from rose hips and green walnuts not only protected guineapigs from scurvy and haemorrhage but improved growth, and often led to increased accumulation of vitamin C in the liver and adrenal glands. Dog-rose hips were of great biological value as source of vitamin C and vitamin P. Vitamin P activity was demonstrated in tea extracts and in the flavone extracts from the dog-rose hip.—W. Hughes.

MARCH, B. and BIELY, J. The effect of ascorbic acid on the growth rate of chicks. *Poultry Sci.*, 1953, **32**, 768-774. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

Chicks were given diets of natural ingredients, adequate or low in folic acid and with or without added ascorbic acid. Some chicks received also an antibiotic or *p*-aminobenzoic acid or both.

Vol. 24, No. 2

When the basal diet was low in folic acid, ascorbic acid increased growth, though to a less extent than folic acid. The growth-stimulating effect of ascorbic acid appeared to depend on the composition of the diet. When the diet contained no added fat or when herring oil was included, only a slight response to ascorbic acid was observed; when it contained cottonseed oil or tallow, the response was greater. Growth was increased by adding penicillin to diets adequate or low in folic acid. When the diet was low in folic acid *p*-aminobenzoic acid increased growth, but a combination with penicillin of *p*-aminobenzoic acid and ascorbic acid, separately or together, stimulated growth more than any of the supplements alone. On a diet considered to be adequate, aureomycin alone or with *p*-aminobenzoic acid did not improve growth, but when aureomycin was given with ascorbic acid growth was slightly but consistently increased.—E. M. Cruickshank.

LINDAN, O. and WORK, E. Experimental liver necrosis in rats. 1. Changes in liver, blood and spleen glutathione and ascorbic acid levels in dietetic liver necrosis. 2. The levels of glutathione and ascorbic acid in livers subjected to acute circulatory congestion in relation to the levels found in dietetic liver necrosis. *Biochem. J.*, 1953, **55**, 554-562; 562-566. [University Coll. Hosp. Med. Sch., London, W.C.1.]

1. With the necrosis-producing diet and conditions of feeding previously reported (Abst. 822, Vol. 21) it was found that in weanling rats the content of reduced glutathione in the liver fell in 13 days to one-quarter, and when necrosis developed to one-tenth, of the normal value. Significant changes occurred in the ratio of oxidised to reduced glutathione. The amount of ascorbic acid was slightly reduced in the pre-necrotic livers and it was absent from necrotic livers. The ratio of total glutathione N to N.P.N. in both pre-necrotic and necrotic livers was about one-third of the normal value. Addition to the experimental diet of cystine or cystine and methionine maintained liver glutathione at its normal value, but tocopherol had no such effect, though it prevented necrosis. The value for reduced glutathione in the spleen was halved and did not change further when necrosis supervened; addition of sulphur-containing amino-acids to the diet restored the value to normal.

The values for reduced glutathione in blood showed a similar trend. The amount of ascorbic acid in the spleen was normal even when it had disappeared from the liver. Pre-necrotic livers had a subnormal water and N content but a raised fat content. Glycogen values were normal.

2. In the livers of adult rats weighing 200 g. acute circulatory congestion was produced by ligation of the base of the left lobe. In some the lobe was amputated and left to autolyse in the abdominal cavity and in others the excised lobe was removed to autolyse *in vitro*. The ligated livers showed values for reduced glutathione, ascorbic acid, N.P.N. and total N, water and glycogen similar to those found in necrosis of dietary origin as reported above. The amputated lobes autolysing in the body cavity gave similar results, but the behaviour of those autolysing *in vitro* showed no resemblance to that of necrotic livers. It is suggested, therefore, that the values for glutathione and ascorbic acid found in liver necrosis caused by diet could be the result of changes occurring in a dead or dying liver left in the body, and were not specific effects of the diet.

WADHWANI, T. K. **Metabolism of fluorine. Absorption, retention, distribution and elimination of fluorine, and its effect on the vitamin C content of different tissues, and on the iodine content of thyroids of rats and monkeys.** *J. Indian Inst. Sci.* [A], 1953, **35**, 354-362. [Sect. Pharmacol., Dept. Biochem., Indian Inst. Sci., Bangalore.]

Young growing rats were maintained on a diet of cottonseed globulin, gelatine, starch, salts and vegetable fat, with vitamin supplements, choline and cystine. The diet contained 0.00045 per cent. F and each rat received daily 2 mg. NaF in water by mouth 1 hr. before feeding. F balances were estimated weekly. After 20 weeks 3 rats were killed and the total F was estimated; in 3 other rats the F content of different tissues was estimated. Of the total of 129.75 mg. F ingested in 20 weeks, 2.45 mg. were in the faeces and 53.96 mg. in the urine, leaving a balance of 73.34 mg. In similar rats on a diet low in Ca and P the balance over a 3-week period was 8.42 mg. from 19.5 mg. ingested. In the first group of animals the average total F recovered in the body, mainly in the skeleton, was 68.80 mg. From some of the rats which had received the experimental diet for 20 weeks the daily dose of 2 mg. NaF was then withheld for 12 weeks, during which time 19.8 mg. F were recovered from the faeces and urine, leaving 51.97 mg. apparently in the body. Total F in the body at death amounted to 47.52 mg. The discrepancies are attributed to errors in the weekly estimations.

In rats and monkeys chronic fluorosis of the same type caused a reduction in the vitamin C content of the soft tissues and a rise in the percentage of I in the thyroid gland, both being more marked in monkeys than in rats.

BREIDENBACH, A. W. and RAY, F. E. **Gastric ascorbic acid in the gastritis guinea pig.** *Science*, 1953, **118**, 557. [Cancer Res. Lab., Univ. Florida, Gainesville.]

Gastritis induced in guineapigs by direct contact of eugenol with the gastric mucosa produced a decrease of 44 per cent. in the ascorbic acid content of the stomach tissue compared with a decrease of 13 per cent. previously found for the rat (Abst. 2117, Vol. 22).—W. Godden.

1864

SOKOLOFF, B., EDDY, W. H., POWELLA, R. BEAUMONT, J. and RELOS, H. **Ascorbic acid analog in experimental cancer.** *Cancer Res.*, 1953, **13**, 639-645. [S. Bio-Res. Lab., Florida Southern Coll., Lakeland.]

D-Glucoascorbic acid added as 1 or 2 per cent. of a Sherman La Mer scorbutogenic diet produced no apparent toxic effect, such as diarrhoea, alopecia or haemorrhage, in rats and mice, but the ascorbic acid concentration in the blood plasma, liver, spleen and adrenal glands fell nearly to zero in 20 days. Intraperitoneal injection of 250 mg. D-glucoascorbic acid per kg. daily did not retard the growth of mouse sarcoma 180 and only slightly inhibited that of Crocker rat carcinoma and mouse adenocarcinoma E 0771. The Sherman La Mer diet with 1 or 2 per cent. D-glucoascorbic acid for 4 weeks considerably retarded the growth of the Crocker rat carcinoma and mouse adenocarcinoma. It retarded also the growth of liposarcoma in guineapigs, but not if the diet was supplemented with an adequate amount of ascorbic acid. In rats on a purified diet containing no ascorbic acid, 1 or 2 per cent. of D-glucoascorbic acid added to the diet lowered the conversion of pteroylglutamic acid to citrovorum factor, but had no effect if 0.1 mg. ascorbic acid was given daily.

ARNDT, C. U. Tierexperimentelle Untersuchungen über die therapeutische und prophylaktische Wirksamkeit der l-Askorbinsäure bei bakteriellen Infektionen. [Animal experiments on the therapeutic and prophylactic action of l-ascorbic acid in bacterial infections.] *Ztschr. ges. inn. Med.*, 1953, **8**, 654-658. [Hyg. Inst., Karl Marx Univ., Leipzig.]

Groups of guineapigs were infected by intraperitoneal injection with *Micrococcus tetragenus* in the same dose, and were given a normal or a scorbutogenic diet; vitamin C was added to both normal and scorbutogenic diet in some series. One group had the deficient diet replaced by the normal diet at the time of infection. The highest death rate occurred in the group having normal diet with added vitamin C, and no significant difference was evident between the other groups. Addition of vitamin C to the normal or deficient diet did not prolong survival. It thus seemed that vitamin C had an unfavourable effect on this infection. It is suggested that the prophylactic use of vitamin C in infections should be advised only in states of deficiency and that even then it is of doubtful value.—A. M. Copping.

DONE, A. K., ELY, R. S., HEISELT, L. R. and KELLEY, V. C. Circulating 17-hydroxycorticosteroids in ascorbic acid-deficient guinea pigs. *Proc. Soc. Exp. Biol. Med.*, 1953, **83**, 722-724. [Lockhart Mem. Lab., Dept. Paediat., Coll. Med., Univ. Utah, Salt Lake City.]

In guineapigs with severe ascorbic acid deficiency, the value for circulating 17-hydroxycorticosteroids was on the average 301.9 ± 43.03 μ g. per 100 ml. and for adrenal ascorbic acid 0.87 ± 0.018 mg. per 100 g., compared with 68.7 ± 19.35 and 35.8 ± 2.66 for similar animals given ascorbic acid for 5 days before being killed, and 32.9 ± 4.60 and 35.5 ± 3.86 for normally fed controls.—W. Godden.

1873

BACCHUS, H. Relation of ascorbic acid nutrition to the *in vitro* metabolism of cortisone by surviving liver tissue. *Endocrinology*, 1953, **53**, 441-446. [Res. Lab., Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

With the method of Porter and Silber (*J. Biol. Chem.*, 1950, **185**, 201) for the estimation of cortisone, it was found that the ability of isolated liver slices from rats or guineapigs to maintain the 17-hydroxy-20:21-diketo structure of cortisone increased when the animals received excess of ascorbic acid and decreased when they were deprived of it. The addition of ascorbic acid to the incubation mixture of livers from deficient animals had no effect.—W. Godden.

1874

CLAYTON, B. E. and PRUNTY, F. T. G. The relation of adrenocortical function to scurvy in guinea-pigs. The effect of exogenous ACTH and adrenalectomy. *J. Endocrinol.*, 1953, **9**, 370-378. [Dept. Chem. Pathol., St. Thomas's Hosp. Med. Sch., London.]

In support of earlier work (Abst. 4910, Vol. 21), it is shown that the gradual rise in the urinary excretion of 17-ketosteroids by guineapigs on a diet deficient in vitamin C, which reaches a peak at the terminal phase, was continued to a still higher level if the animals received injections of adrenocorticotrophic hormone during the last few days when they were losing weight. Animals from which both adrenal glands had been removed and which were deprived of ascorbic acid lost weight rapidly and died in from 3 to 7 days without showing any increase in urinary 17-ketosteroids, or any response in this respect to adrenocorticotrophic hormone.—W. Godden.

- SCHILLING, J. A., RADAKOVICH, M., FAVATA, B. V., FILER, L. J. (Jr.) and JESPERSEN, H. W. The relationship of vitamin C and ACTH in experimental wounds. *Surg. Gynecol. Obstet.*, 1953, **97**, 434-438. [Dept. Surg., Sch. Med. Dent., Rochester, N.Y.]

Wound healing in male guineapigs was studied by means of subcutaneously implanted tantalum wire mesh cylinders, by measurement of planimeter tracings from photographs of wound closure and by measurement of tensile strength of primarily closed linear wounds. There were 6 groups, 4 on normal diet alone or with added vitamin C or injected adrenocorticotrophic hormone (ACTH) or both, and 2 on scorbutogenic diet alone or with ACTH. There was no significant effect of ACTH on the healing process or any combined effect of it with vitamin C. The vitamin C level in the blood serum showed irregular fluctuations in phases of wound healing; in the tissue juice from the mesh cylinders the fluctuations were much greater and seemed to be independent of the administration of vitamin C or ACTH.—W. Godden.

(P.S.) da vila hípica do Jockey Club de São Paulo. [Ascorbic acid in whole blood of thoroughbred racehorses of the Jockey Club, São Paulo.] *Rev. Fac. Med. vet., São Paulo*, 1952, **4**, 513-522. [Dept. Quim. Ord., Univ. São Paulo, Brazil.] English summary.

Ascorbic acid was estimated by the diphenylhydrazine method in whole blood from 117 thoroughbred racehorses aged from 2 to 8 years. The horses were in active training and received rations of cereals and green fodder of ample vitamin C content. No significant difference was found between the average values for males and females; the mean for the whole group was 0.633 ± 0.013 mg. per 100 ml. blood.—A. M. Copping.

1881

- GYLLENBERG, H., ROSSANDER, M. and ROINE, P. Askorbiinihapon ja dehydroaskorbiinihapon määristä maidossa eri käsittely- ja säilytysvaihkeissa. [Ascorbic and dehydroascorbic acid in milk under different conditions of handling and storage.] *Maataloust. Aikakausk.*, 1953, **25**, 99-112. [Dept. Nutrit. Chem., Univ. Helsinki.] English summary.

The vitamin C in freshly drawn milk was almost entirely ascorbic acid. Exposure to diffuse daylight caused oxidation to dehydroascorbic acid but no further change. In direct sunlight the dehydroascorbic acid rapidly disappeared, with an abrupt fall in total vitamin C potency. Aeration of milk accelerated the oxidation. The content of total vitamin C in market milk was about the same in summer, autumn and winter, but the proportion present as ascorbic acid was distinctly less in summer. Storage at 0° C. caused marked oxidation of ascorbic acid but not of dehydroascorbic acid; at 18° C. most of the latter disappeared, but loss of ascorbic acid was small. (From summary.)

- ORR, K. J., DENNING, H. and MILLER, C. D. The sugar and ascorbic acid content of papayas in relation to fruit quality. *Food Res.*, 1953, **18**, 532-537. [Food and Nutrit. Dept., Univ. Hawaii, Honolulu.]

Samples of Solo papaya, Line No. 5, were collected at monthly intervals from February to December 1950, analysed for ascorbic acid, total sugars, moisture and pH, and graded organoleptically. Ascorbic acid, sugars and the scores for colour, flavour and sweetness showed significant monthly changes, the fruit having the best quality from May to November when the content of sugar and ascorbic acid was highest. The position of the fruit on the tree appeared to affect its content of sugar but not of ascorbic acid or its organoleptic score.—W. Godden.

1883

SIDDAPPA, G. S. Vitamin C in amte kayi (Indian hog plum). *Bull. Central Food Technol. Res. Inst. Mysore*, 1953, **2**, 286-287. [Div. Fruit Technol., C.F.T.R.I., Mysore.]

The true ascorbic acid content of the fully mature green fruit of the Indian hog plum, *Spondias pinnata*, Kurz, was from 6 to 11 mg. per 100 g. fresh material.—W. Godden.

1884

HELLSTRÖM, V. Die Haltbarkeit des Vitamins C bei der Zerkleinerung von rohen Vegetabilien. [Stability of vitamin C in shredded raw vegetables.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1952-53, **5**, 98-113. [Vitaminabt., Staatl. Inst. Volksgesundh., Tomtebodav., Stockholm.] French and English summaries.

The literature is reviewed. White cabbage and tomatoes were mashed to a fine pulp in a Turmix apparatus, which resembles a Waring Blendor, and stored for periods of up to 24 hr. The values for the uncut vegetables were obtained by mashing in the presence of metaphosphoric acid. Ascorbic acid, dehydroascorbic acid and total ascorbic acid were estimated by indophenol titration before and after treatment with H_2S . The values for free ascorbic acid were decreased in mashed vegetables even when fresh, but the total ascorbic acid activity was only slightly decreased after 10 min. in the mixer. When the mashed cabbage had stood for 1 hr., from 20 to 30 per cent. of the total ascorbic acid was lost. In the tomato pulp there was little loss in 4 hr. and only about 40 per cent. in 24 hr. Cabbage lost up to 90 per cent. of its total ascorbic acid activity in 24 hr. Addition of lemon juice to chopped cabbage or tomato decreased the loss of ascorbic acid during storage; it had a protective effect on both ascorbic and dehydroascorbic acid, which appeared to be related to its action in lowering the pH of the chopped vegetables.—A. M. Copping.

1885

PAUL, P. C., ROBERTSON, W. F., CASE, W. H. and MARSHALL, R. E. Nutritive value of canned foods. **44. Enzyme inactivation and ascorbic acid retention in vegetables blanched and held under different conditions prior to canning.** *Food Technol.*, 1952, **6**, 464-467. [Dept. Foods Nutrit., Michigan State Coll.]

A comparison was made of the effects of blanching at high temperature, 200° to 212° F., and at low temperature, 170° to 180° F., and of treatment after blanching and before canning on the inactivation of catalase and peroxidase, and on the ascorbic acid content of asparagus, peas, green beans, Lima beans and spinach. The results for ascorbic acid

are in general agreement with those of earlier workers. Both temperature and duration of blanching affected the inactivation of the enzymes. There was no definite trend of change in enzyme activity with treatment after blanching. There was no clear-cut relation between degree of enzyme inactivation and loss of ascorbic acid.—W. Godden.

DAMANSKI, A. F., NIKOLAEFF-MARIC, T. K. and BAKARIC, M. E. Rapport entre vitamine C et cellulose dans l'épinard et dans les pommes de terre. [Relation between vitamin C and cellulose in spinach and potatoes.] *Bull. Soc. Chim. biol.*, 1953, **35**, 981-983.

1887

ZOTOVA, O. N. Vliyanie nekotorykh uslovii vyrashchivaniya kartofelya na sodержание vitamina C. [The effect of certain conditions of cultivation on the vitamin C content of potatoes.] *Biokhimiya*, 1953, **18**, 205-209. [Kaf. Khran., Omsk. Sel'skhoz. Inst. Im. S.M. Kirova.]

Experiments on potato cultivation near Omsk, Siberia, showed that the nature of the soil, soil moisture, conditions of growth and variety all affected the vitamin C content. The value was higher in potatoes grown on light clay than on heavy clay. Spraying reduced the vitamin C content only slightly whether the season was wet or dry. Early varieties had a greater vitamin C content than others. The vitamin C content of Siberian varieties was intermediate between that of far-northern and far-eastern varieties and that of central and south-western varieties.

W. Hughes.

KOTT, V. Dynamika obsahu l-askorbové kyseliny v ovoci za vegetace. [The dynamics of the L-ascorbic acid content of fruits in the course of vegetation.] *Sborn. čsl. Akad. Zěměd.*, 1953, **26**, 427-446. [Výzkumný Ústav Potravinářské Tech., Prague.] Russian and English summaries.

Ascorbic acid was estimated in 6 varieties of cherries, 1 of apples and 2 of pears at different stages of maturity. The content in the fruits was always highest at the early stages of development when the seeds or kernels were soft or undeveloped. It then fell rapidly and rose slightly again until the fruit attained physiological maturity. The biggest difference in ascorbic acid content between peel and pulp was in the early stages of development in apples, but in pears it was in the last stages of ripening. (From summary.)

GLEICHWEIT, E. Der Einfluss des Wirkstoff-Komplexes T auf Wachstum und Entwicklung des Goldhamsters (*Cricetus* [*Mesocricetus*] *auratus* Waterhouse). [Action of the factor T complex on the growth and development of the golden hamster.] *Ztschr. Vitamin-, Hormon-*

Fermentforsch., 1952-53, **5**, 249-264. [Zool. Inst., Univ. Graz.] French and English summaries.

The descendants of a single pair of golden hamsters were maintained on a diet of grains, black or white bread dried, green food and skimmed milk. Factor T was given in milk or directly into the mouth with a pipette [no dose mentioned]. It was given to the mother during gestation or lactation or to the young from the moment they could eat. In all, 72 litters including 435 individuals were used. Young hamsters receiving factor T in the different ways showed a very small superiority in growth over young animals not given factor T. When the mother was given vitamin E as well as factor T from mating, the superiority in growth was a little greater.—E. M. Hume.

KUNG, J. T., HANRAHAN, V. M. and CALDWELL, M. L. A comparison of the action of several alpha amylases upon a linear fraction from corn starch. *J. Amer. Chem. Soc.*, 1953, **75**, 5548-5554. [Dept. Chem., Columbia Univ., New York.]

The linear fraction from maize starch was prepared by the method of Lansky *et al.* (*J. Amer. Chem. Soc.*, 1949, **71**, 4066) and the activities of 10 amylases were tested by their blue values with starch and estimation of their reducing powers.

Human pancreatic and salivary enzymes from the same or different persons had the same activity, and rat amylases from pancreas, liver, spleen and blood serum had activities similar to each other and to those of the human enzymes. Amylases from pig pancreas and pig saliva differed in activity from one another and from human and rat preparations. Taka amylase and amylase from *Bacterium subtilis* differed from each other and from the others.

The differences occurred in the early stages of hydrolysis when less than 25 per cent. of the glucosidic linkages of the substrate had been broken.—D. Harvey.

TOTTER, J. R., BURNETT, W. T. (Jr.), MONROE, R. A., WHITNEY, I. B. and COMAR, C. L. Evidence that molybdenum is a nondialyzable component of xanthine oxidase. *Science*, 1953, **118**, 555. [Biol. Div., Oak Ridge Nat. Lab., Tenn.]

Labelled sodium molybdate was injected intravenously into a cow, and xanthine oxidase was isolated by Ball's method (Abst. 1572, Vol. 9) from milk collected one to several days thereafter. The preparation was treated twice with 25 to 40 per cent. ammonium sulphate, after which dialysis for 20 or 40 hr. had no effect on the ratio of ^{99}Mo to xanthine oxidase activity. Spectrophotometric data suggest a molar ratio of flavin to Mo of 2:1. The results were not affected by mixing radioactive with inactive milk before isolation of the xanthine oxidase.—W. Godden.

1905

BOWIE, J. Y., DARLOW, G. and MURRAY, M. M. **The effect of sodium fluoride on gastric acid secretion.** *J. Physiol.*, 1953, **122**, 203–208. [Physiol. Lab., Bedford Coll., Univ. London, N.W.1.]

The effects of placing NaF in the stomach of anaesthetised cats were studied by measuring the response in acid secretion to injections of histamine. Inhibition was marked with concentrations of NaF above 0.005 M, and it is suggested that this may be due to an effect on the membrane of the oxyntic cells which results in an alteration of permeability to H ions.—D. Harvey.

1906

HELE, M. P. **The phosphorylation and absorption of sugars in the rat. 1. Hexokinase activity**

in the intestinal mucosa. 2. Sugar absorption *in vivo*, and its relationship to the phosphorylation of sugar *in vitro*. *Biochem. J.*, 1953, **55**, 857-863; 864-867. [Biochem. Lab., Univ. Cambridge.]

1. Adult rats were maintained on a diet containing rice starch 40, sucrose 17, light white casein 23, arachis oil 15, salt mixture 5, dried yeast 7.5 and cod liver oil 2.5 parts [given as percentages, but they add up to 110]. They were killed without being fasted. Homogenates were prepared from the whole small intestine.

The rate of hexokinase reaction at 0.005 *M* glucose or 0.028 *M* fructose increased with the adenosine triphosphate (ATP) concentration over the range 0.013 to 0.04 *M*, but with 0.0055 *M* fructose the rate was unaffected by ATP concentration. At constant ATP concentration the rate of hexokinase reaction dropped sharply with increase of glucose concentration from 0.0055 to 0.016 *M*, but then rose sharply to the original rate at 0.028 *M*. Reaction with fructose at constant ATP concentration increased steadily with increasing fructose concentration to a steady maximum at 0.022 *M* fructose. Mannose and xylose had effects similar to those of fructose, and galactose to those of glucose. The rate of phosphorylation of mixtures never equalled the sum of the components.

It is concluded that the differences in phosphorylation rates of glucose and fructose are due to a property of the hexokinase, and the possibility exists that there are two or more hexokinases in intestinal mucosa.

2. Sugar absorption from the small intestine was studied in anaesthetised rats after fasting for 48 hr. The absorption rate ratios of different sugars were similar to their phosphorylation rate ratios obtained as in the preceding paper. The total phosphorylating capacity of the intestinal mucosa was more than enough to account for phosphorylation of all the sugar absorbed during experiments *in vivo*.—D. Duncan.

1907

PONZ, F. Inhibición de la absorción selectiva de glucosa por el molibdato. [Inhibition of the selective absorption of glucose by molybdate.] *Rev. española Fisiol.*, 1953, **9**, 37-42. [Lab. Fisiol. Animal, Univ. Barcelona.] English summary.

Ammonium molybdate in concentrations from 0.005 *M* to 0.05 *M* was added to 5.4 per cent. glucose solutions to test the effect of molybdate on intestinal absorption of glucose in the rat. Successive absorption tests were made with each concentration on 5 animals, the first and third with glucose alone, the second and fourth with added molybdate. With 0.005 *M* molybdate there

was no effect on glucose absorption, but inhibition was evident with 0.025 *M* solutions. A concentration of 0.05 *M* caused inhibition by 20 to 50 per cent. in the first absorption test and 30 to 70 per cent. in the second. Washing the intestinal loop with saline after absorption of a glucose-molybdate solution did not restore normal absorption of glucose. In experiments made with 2 similar loops in one animal, absorption of 0.05 *M* molybdate from an isotonic NaCl solution in one loop did not inhibit glucose absorption in the adjoining loop. This indicated that the inhibiting effects of molybdate in the first tests were not caused by inhibition of the central mechanism, but were presumably due to a local effect of the molybdate on the epithelial cells.—M. B. Richards.

1908

LLUCH, M. and PONZ, F. Inhibición de la absorción intestinal de glucosa por el cerio. [Inhibition by cerium of absorption of glucose from the intestine.] *Rev. española Fisiol.*, 1953, **9**, 135-142. [Lab. Fisiol. Animal, Fac. Sci., Univ. Barcelona.] English summary.

1909

WILD, C., REYMOND, C. and VANNOTTI, A. Contribution à l'étude de la résorption des acides aminés. [Absorption of amino-acids.] *Schweiz. med. Wochenschr.*, 1953, **83**, 894-897. [Clin. Méd., Univ. Lausanne.]

The absorption of a balanced mixture of amino-acids was studied in subjects over 70 years of age and in a group of the middle-aged. In the old people the rise of amino-N in the blood was much less than in the middle-aged subjects. Increasing the amount of amino-acids given did not cause an equivalent increase of blood amino-N in either group. A greater increase of amino-N was observed in old subjects given an unbalanced mixture lacking tryptophan. Administration of B vitamins or of pancreatin before the amino-acid mixture improved its absorption in old subjects. Studies of N excretion, of blood sugar, lactic acid and pyruvic acid and of basal metabolism did not suggest increased utilisation of amino-acids in old age, but rather a slower process of absorption. Both absorption and utilisation were improved in the presence of B vitamins.—A. M. Copping.

1910

PFISTERER, H. Milch- und Zuckerempfindlichkeit nach Magenresektion. [Sensitivity to milk or sugar after resection of the stomach.] *Langenbecks Arch. klin. Chirurg.*, 1953, **275**, 528-543. [Chirurg. Klin., Univ. Cologne.]

In the author's view, nausea after milk or sugar is due not to failure to digest milk protein, to milk

allergy or to alimentary hypoglycaemia, but to a disturbance of absorption of sugar from the intestine, and the offending substance is the α -lactose in cow's milk.

During gastric resection for ulcer, glucose solution with barium was installed into the stomach remnant, closed duodenal stump or afferent jejunal loop (20 patients for each) and β -lactose solution into the 2 latter organs (10 patients for each) and the subsequent events were followed by X-rays and blood sugar estimations; blood sugar estimations were also made in 5 patients given no sugar, to rule out the effects of anaesthetic and operative trauma. Absorption of glucose was most rapid from the duodenum; blood sugar rose to a peak of 186 mg. per 100 ml. in about $\frac{1}{2}$ hr., then fell to nearly normal, with a second rise after about 2 hr. when the glucose had moved on to the jejunum. After instillation of glucose into the jejunum the early rise in blood sugar was even higher, but after 1 hr. it fell rapidly to about 80 mg. and there was no second rise. After instillation into the stomach remnant, blood sugar rose slowly to about 130 mg. after 4 hr. Absorption of β -lactose followed much the same course from both duodenum and jejunum; the peak value was reached after about 50 min. and the fall was less rapid than with glucose.

Similar differences in blood sugar curves were found when 40 patients 2 or 3 weeks after gastric resection were given 300 g. warm milk sweetened with 50 g. glucose and, a few days later, 300 g. of a dried milk preparation (Alete-Frühnahrung) with 25 g. β -lactose. Unpleasant symptoms occurred in 18 patients in the first test, but in only 2 in the second, though there was no significant difference in blood sugar curves.

These findings are taken to show that different sugars are acted on by specific enzymes located in different parts of the small intestine and to support Malyoth's hypothesis of the ready absorption of β -lactose.—W. M. Deans.

1911

STEINGRÄBER, M. and BURMEISTER, H. Untersuchungen über die Resorption von Eiweiss und Fett nach totaler Magenentfernung. [Absorption of protein and fat after total gastrectomy.] *Ztschr. ges. inn. Med.*, 1953, **8**, 737–741. [Chirurg. Klin. Charité, Univ. Berlin.]

The relative loss of fat and protein caused by rapid excretion was studied in normal subjects and in patients from whom part or all of the stomach had been removed, with anastomoses involving the oesophagus and duodenum or special loops of the intestine according to the technique of Tomoda or Graham. Total gastrectomy caused more serious loss of nutrients than partial resection, and the

extent of the loss depended on the type of anastomosis. The most effective techniques appeared to be those of Tomoda or Graham by which the passage of the partly digested food into the intestine was longer delayed. The percentage loss of energy in 2 such cases was 9.4 and 5.0, in comparison with 15.7, 25.6 and 35.8 in 3 other patients. In direct oesophago-jejuno-stomy and oesophago-duodenostomy great loss of fat occurred, which could be prevented to a considerable extent by satisfactory anastomoses.—A. M. Copping.

1912

BRAIN, R. H. F. Steatorrhoea in oesophago-gastric surgical practice. *Proc. Roy. Soc. Med.*, 1953, **46**, 438–444.

In continuation of previous work (Abst. 2756, Vol. 21), chronic malnutrition after subtotal gastrectomy in which the pyloric canal and pylorus were retained, or after oesophago-jejuno-stomy with the intact normal stomach left *in situ*, is discussed and representative cases are described. In all 4 patients fat balance tests showed only mild impairment of fat absorption, which could be overcome by frequent high-fat meals; the patients' loss of weight was ascribed to low food intake, due to the dumping syndrome or to oesophagitis from regurgitation of intestinal contents. On the other hand, a patient in whom the stomach was not removed and the lower oesophagus was replaced by an isolated portion of jejunum had a normal capacity for food and normal fat absorption and gained 13 lb. in the first year after operation.

W. M. Deans.

1913

MONTINI, T. and PONTREMOLI, S. Sui rapporti tra potere deidrogenante della bile e assorbimento enterico dei grassi. [Relation between the dehydrogenating activity of the bile and the intestinal absorption of fats.] *Arch. Fisiol.*, 1953, **53**, 84–93. [Ist. Fisiol., Univ. Genoa.] English summary.

Dogs with Thiry Vella loops in the intestine received 5 ml. of 20 per cent. emulsion of coconut oil, introduced into the loop with or without addition of ox bile heated at 100° C. for 30 min. or unheated. The mixture was withdrawn 30 min. later and the amount and iodine value of the fat were estimated. The dogs were then depancreatised and the experiment was repeated.

Before pancreatectomy the percentage of fat absorbed was 45 with no addition, 47 with heated ox bile and 60 with unheated ox bile. The corresponding values after pancreatectomy were 0, 19 and 35. The I value of the fat after withdrawal was always higher in the intact dogs, being highest with unheated ox bile. The I value also rose when coconut oil was incubated *in vitro* with ox bile, but not with heated ox bile. In further similar

tests *in vivo*, bile salts heated or unheated exercised a small effect in promoting absorption, but none in raising the I value. Bile of normal dogs behaved like ox bile, but bile from depancreatized dogs, whether it was heated or unheated, had no more action than heated bile from normal dogs.
